In 1897 a new and more complicated classification was introduced. The word "burlap" was omitted. One reason for the omission was probably the confusion that had arisen from the attempt to confine the word to cloths of jute. Bags were then classified on the basis of (1) weave—whether woven plain or not; (2) threads per square inch; and (3) whether unprocessed or processed. Imports of bags which had not been processed, by dyeing, printing, etc., and which had been manufactured from a cloth plain woven of single jute yarn, not exceeding 30 threads to the square inch, fell under a specific paragraph. The paragraph imposed a compound duty of seven-eighths of a cent per pound and 15 per cent ad valorem, a differential of one-fourth of 1 cent per pound over the cloth commonly used for bag-making purposes.

This classification and rate of duty were reenacted without change by the act of 1909. However, the differential between the bags and the cloth from which made was lowered one-sixteenth of a cent.

Under the act of 1913, bags, if made from plain woven cloth of single jute yarn and not processed, were dutiable at 10 per cent; if made from a cloth not plain woven, or one which has been processed, at 35 per cent ad valorem. Plain woven unprocessed jute cloths were free of duty, whereas those which had been processed were assessed at 10 per cent. Cloths not plain woven, such as twilled, were dutiable at 35 per cent.

The act of 1922 provides for bags or sacks made from fabrics composed wholly of jute, regardless of whether the fabric is plain woven or twilled or whether it is of single yarn or other than single yarn, at 1 cent per pound plus 10 per centum ad valorem when unprocessed, and 1 cent per pound plus 15 per centum ad valorem when processed—that is, bleached, dyed, printed, etc. The fabric, when either plain woven or other than plain woven, whether of single yarn or not, is dutiable at 1 cent per pound when not processed and at 1 cent per pound plus 10 per centum ad valorem when processed. These rates produce a 10 per cent differential on bags or sacks made from unprocessed fabric and a 5 per cent differential on bags or sacks made from processed fabric.

COTTON BAGS.

Cotton bags were specifically mentioned in one tariff act, that of 1872. The reference reads as follows:

On all bags, cotton bags and bagging, and all other like manufactures not herein otherwise provided for, except bagging for cotton composed wholly or in part of flax, hemp, jute, gunny cloth, gunny bags, or other material, 40 per centum ad valorem.

EFFECT OF TARIFFS ON IMPORTS.

Changes in tariff rates and tariff classifications during the last 30 years have only temporarily influenced imports for consumption. For instance, during the fiscal years 1892–1894, the three full years in which the act of 1890 was in force, imports of bags ranged between 28,129,000 and 25,875,000 pounds; the act of 1890 classified bags as "bags for grain made of burlaps" and assessed them at 2 cents a pound, which was equal to a duty of about 50 per cent. The elimination of this duty by the act of 1894 caused a twofold increase in the consumption of foreign bags. In the period 1895–1897 imports averaged about 50,000,000 pounds yearly. The passage of the act of 1897, which classified bags on the basis of threads per square inch, and according to whether the fabrics were processed or unprocessed, and which levied a compound duty of seven-eighths cent per pound and 15 per cent ad valorem, resulted in imports for consumption in 1899 contracting to the level existing in 1892–1894. The equivalent ad valorem of this compound rate which was subsequently reenacted in 1909 ranged in the years 1899–1913 between 35.41 and 25.75 per cent. From a total in 1899, amounting to 26,960,000 pounds, imports showed a marked tendency to increase. At one extreme stands the total of 30,037,000 pounds, in 1904; and at the other a total of 60,624,000 pounds in 1910. The decided and even growth of consumption of foreign bags during the period 1897–1913 may be judged from the fact that in the years 1900–1904 yearly consumption averaged 41,403,000 pounds, and in the years 1905–1909, 48,885,000 pounds.

With the passage of the act of 1913, which lowered the duty on bags to an ad valorem rate of 10 per cent, imports with 62,875,000 pounds for the fiscal year ended June 30, 1914, reached a new level. From this peak imports declined to 51,000,000 and 54,000,000 pounds for the years 1915 and 1916, and dropped to 35,000,000 pounds for 1917 and to 31,000,000 pounds for 1918.

Imports remained below the pre-war level during 1919 and 1920 when they amounted to 39,385,000 pounds and 38,799,000 pounds, respectively, but in 1921 they amounted to 70,632,965 pounds, which is somewhat in excess of the pre-war level.

STATISTICAL TABLES.

Production of bags other than paper in United States, by States, 1904–1919.

[From Federal Census.]

State.	1904	1909	1914	1919
California	$2,504,436			$13,414,851
Georgia		$604,366	$698,000	1,553,115
Illinois	808,784	965,442	2,876,000	7,933,704
Louisiana	4,076,226	5,351,661	7,804,000	18,310,111
Missouri	6,612,494			38,020,623
New York	3,647,701	4,986,279	8,962,000	26,821,937
North Carolina	1,310,742			
Ohio	1,500,754			
Oregon	957,000			
Pennsylvania	3,303,998			6,979,582
Tennessee		2,290,992	3,246,000	12,318,292
Virginia	216,863			4,840,831
All other	12,460,089	40,682,882	55,463,000	83,866,428
Total	37,399,087	54,881,622	79,049,000	214,059,474

Production of jute bags in the United States, 1917, 1918.

[From Census of War Commodities,[1] 1918—Textile fibers.]

	1917	1918[2]
	Number.	*Number.*
Sugar bags	9,144,995	4,357,978
Other bags:		
Under 10-ounce burlap	176,129,607	183,623,504
10-ounce burlap and over	157,711,032	156,152,534
Total	342,985,634	344,134,016

[1] 3,473 establishments engaged in jute trade or industry.
[2] Actual production for 5 months, Jan. 1–May 31, 1918. Estimated production for 7 months, June–December, 1918.

		Valued at 5 cents per pound or less.....	Do.
		Valued above 5 cents per pound.....	40 per cent ad valorem.
1894....	277	All manufactures of flax, hemp, jute, or other vegetable fiber, except cotton, or of which these substances or either of them is the component material of chief value, not specially provided for in this act.	35 per cent ad valorem.
	424½	Burlaps, and bags for grain made of burlaps.....	Free.
1897....	343	Bags or sacks made from plain woven fabrics, of single jute yarns, not dyed, colored, stained, painted, printed, or bleached, and not exceeding 30 threads to the square inch, counting the warp and filling.	⅛ cent per pound and 15 per cent ad valorem.
	347	All manufactures of flax, hemp, ramie, or other vegetable fiber, or of which these substances, or either of them, is the component material of chief value, not specially provided for in this act.	45 per cent ad valorem.
1909....	354	Bags or sacks made from plain woven fabrics, of single jute yarns, not dyed, colored, stained, painted, printed, or bleached, and not exceeding 30 threads to the square inch, counting the warp and filling.	⅛ cent per pound and 15 per cent ad valorem.
	358	* * * all manufactures of flax, hemp, ramie, or other vegetable fiber, or of which these substances, or any of them, is the component material of chief value, not specially provided for in this section.	45 per cent ad valorem.

Rates of duty, bags of jute or cotton, 1883–1922—Continued.

Act of—	Par.	Tariff classification or description.	Rate of duty.
1913....	281	Bags or sacks made from plain woven fabrics, of single jute yarns, not dyed, colored, painted, printed, or bleached.	10 per cent ad valorem.
	284	* * * all manufactures of flax, hemp, ramie, or other vegetable fiber, or of which these substances, or any of them, is the component material of chief value, not specially provided for in this section.	35 per cent ad valorem
1922....	1018	Bags or sacks made from plain woven fabrics of single jute yarns or from twilled or other fabrics composed wholly of jute—	
		Not bleached, printed, stenciled, painted, dyed, colored, nor rendered noninflammable.	1 cent per pound and 10 per centum ad valorem;
		Bleached, printed, stenciled, painted, dyed, colored, or rendered noninflammable.	1 cent per pound and 15 per centum ad valorem.
	1021	* * * all manufactures of vegetable fiber other than cotton, or of which such fibers or any of them is the component material of chief value, not specially provided for. (Bags of cotton, as heretofore, fall within the general provisions for manufactures of cotton.)	40 per centum ad valorem.

Court and Treasury Decisions.

Secondhand bags made from plain woven jute fabrics, containing identification marks consisting of two or three letters stenciled thereon and covering an insignificant amount of the surface of the bags, are not dyed, colored, stained, painted, or printed, within this paragraph, and are dutiable thereunder, rather than as manufactures of vegetable fiber under paragraph 284. (G. A. 7705, T. D. 35268, of 1915.) Similar bags, stenciled with identification marks or with the words "for drawback" with the name of the manufacturer (Abstract 38362, of 1915) and having words, letters, and numbers stenciled thereon for identification only (Abstract 38434, of 1915) were also classified under this paragraph. However, jute bags having a substantial portion of their surface dyed, colored, stained, painted, or printed, although by stenciling, and not for identification, are excluded from this paragraph and are dutiable under paragraph 284, G. A. 5177, T. D. 23870, of 1902, cited. (G. A. 8058, T. D. 37158, of 1917.) Bags with a brand covering about one-third of the surface and for other than mere identification were likewise excluded from this paragraph following the last-mentioned case. (Abstract 42569, of 1918.)

Bags with a colored stripe down the center of each side composed of a single jute yarn of the warp, trivial in value and character and not constituting a necessary or substantial part of the article, were held not to be colored or dyed. (G. A. 5105, T. D. 23618, of 1902.) Bags with two stripes of colored yarns on each side, constituting about 7.5 per cent of the warp (G. A. 4997, T. D. 23286, of 1901) and bags with a colored stripe about 1 inch wide down the center of each side composed of five warp threads (G. A. 5105, T. D. 23618, of 1902) were excluded from the provision "not dyed, colored, etc.," and are dutiable under paragraph 284.

Twilled jute bags are not within this paragraph as made from plain woven fabrics, but are likewise dutiable under paragraph 284. (Abstract 37088, T. D. 35020, of 1914, following G. A. 6063, T. D. 26445, of 1905.)

Old secondhand jute bags, twill woven or colored, which had become so worn, torn, and cut as to be unsuitable for reuse as bags,

but which were shown to be almost entirely used for the patching of cotton bales and for the covering of barrel heads, etc., were held dutiable under paragraph 384 of the act of 1913 as waste not specifically provided for, and not under paragraph 284 as manufactures of vegetable fiber. (G. A. 8374, T. D. 38506, of 1920.) Jute sugar bags, twill woven and printed, apparently of whole and sound fabric, with the exception that some of them were sticky with sugar, but which the appraiser reported could be used as containers after being washed, and which were indiscriminately mixed, were held dutiable under paragraph 284 as manufactures of vegetable fiber. (G. A. 8397, T. D. 38572, of 1920.)

APPENDIX.

Since the preparation of this survey the tariff act of 1922 has been enacted. It changes the classifications and provides rates of duty different from those fixed in the act of 1913, but the effect of these differences on the relationship of the domestic to the foreign industry can not be definitely measured until imports have been recorded under the new provisions.

The text of the act of 1913 and of the act of 1922 relating to bags of jute or cotton follows:

Act of 1913.	Act of 1922.
PAR. 231. Bags or sacks made from plain woven fabrics, of single jute yarns, not dyed, colored, stained, painted, printed, or bleached, 10 per centum ad valorem.	PAR. 1018. Bags or sacks made from plain woven fabrics of single jute yarns or from twilled or other fabrics composed wholly of jute, not bleached, printed, stenciled, painted, dyed, colored, nor rendered noninflammable, 1 cent per pound and 10 per centum ad valorem; bleached, printed, stenciled, painted, dyed, colored, or rendered noninflammable, 1 cent per pound and 15 per centum ad valorem.
PAR. 284. All woven articles, finished or unfinished, and all manufactures of flax, hemp, ramie, or other vegetable fiber, or of which these substances, or any of them, is the component material of chief value, not specially provided for in this section, 35 per centum ad valorem.	
PAR. 266. All articles made from cotton cloth, whether finished or unfinished, and all manufactures of cotton or of which cotton is the component material of chief value, not specially provided for in this section, 30 per centum ad valorem.	PAR. 921. All articles made from cotton cloth, whether finished or unfinished, and all manufactures of cotton or of which cotton is the component material of chief value, not specially provided for, 40 per centum ad valorem.

A further comparison, relating to rates and differentials on jute fabrics and bags or sacks made from such fabrics, follows:

	Rate.			Differential.	
	Act of 1913.	Act of 1922.		Act of 1913.	Act of 1922.
	Ad valorem.	Specific (per pound).	Ad valorem.		
Plain woven fabric:	*Per cent.*	*Cents.*	*Per cent.*	*Per cent.*	*Per cent.*
Of single jute yarn—					
Not processed	Free.	1			
Processed	10	1	10		
Of other than single jute yarn—					
Not processed	35	1			
Processed	35	1	10		
Bags made from plain woven fabric:					
Of single jute yarn—					
Not processed	10	1	10	10	10
Processed	35	1	15	25	5
Of other than single jute yarn—					
Not processed	35	1	10	None.	10
Processed	35	1	15	None.	5
Jute fabric other than plain woven, of single or other than single jute yarn:					
Not processed	35	1			
Processed	35	1	10		
Bags made of jute fabric other than plain woven, of single or other than single jute yarn:					
Not processed	35	1	10	None.	10
Processed	35	1	15	None.	5

The act of 1913 provided a 10 per cent differential on bags or sacks made from non-processed, plain woven fabric of single jute yarn, and this differential is the same in the act of 1922. When the same sort of bags or sacks are made from processed fabric, however, the differential is 5 per cent in the act of 1922 as against 25 per cent in the act of 1913. The 25 per cent differential in the act of 1913 did not result from legislative intent but existed rather by reason of the fact that these articles were not specially provided for and fell under the basket paragraph (284) at 35 per cent ad valorem, while the fabric from which they are made was specially provided for at 10 per cent ad valorem in paragraph 279.

Other differentials provided in the act of 1922 did not exist under the act of 1913.

It should be noted that domestic manufacturers have held that the production of jute bags other than burlap in the United States could not be profitably undertaken in competition with India without a differential between the duty on the twilled cloth used in the manufacture of such bags and the duty on the finished bag (p. 21).

Bags produced in the United States are printed with various brands, as ordered, whereas, owing to India's limited facilities for printing and the fact that an additional duty of 25 per cent ad valorem was levied on printed bags under the act of 1913, imported bags have been unprinted (p. 20). The act of 1922, as before pointed out, levies an additional duty of 5 per cent on bags made from fabric which has been printed or otherwise processed.

The jute manufacturing industry in India is primarily engaged in the production of cloth. The domestic industry encounters competition in but one class of bag, the California or Pacific coast cental, which is a standard bag, unprinted, that is used in large quantities.

PREFACE.

This is one of a series of Tariff Information Surveys prepared by the United States Tariff Commission. These surveys have been prepared in accordance with the provisions of the tariff act in force at the time of their preparation and cover all the articles and commodities provided for in the acts of 1913 and 1922, and others not specially provided for.

In some cases two or more paragraphs have been combined in one survey. In doing this, industrial relationship of the articles has been considered. In those instances where an article or a commodity has been treated under a preceding paragraph, reference to this fact is made. In cases where one grade of an article or commodity is dutiable and another grade of the same article or commodity is on the free list, the entire treatment is carried out under the dutiable paragraph.

A separate pamphlet listing the principal subjects investigated and reported upon has been published. It contains:

(1) An alphabetical index of the articles and commodities provided for in the tariff acts of 1913 and 1922, showing the paragraph in the acts in which the article or commodity is provided for, and, if discussed under a different paragraph, the number of such paragraph.

(2) The number of the survey in which the article or commodity is discussed.

Special and miscellaneous reports, which are unnumbered, are also included in the index.

Thus, by use of the index, the exact location of the survey or report relating to a given article or commodity can be ascertained.

In the preparation of this report the Tariff Commission had the services of Daniel W. Alexander, of the textile division of the commission's staff, and of others.

CONTENTS.

WOVEN FABRICS OF FLAX, HEMP, OR RAMIE.

SECTION I.

FLAX, HEMP, OR RAMIE FABRICS, PLAIN OR FIGURED.

(Not including pile fabrics or table damask.)

TARIFF ACT OF 1922.

Paragraph 1009. Woven fabrics, not including articles finished or unfinished, of flax, hemp, or ramie, or of which these substances or any of them is the component material of chief value (except such as are commonly used as paddings or interlinings in clothing), exceeding 30 and not exceeding 100 threads to the square inch, counting the warp and filling, weighing not less than 4½ and not more than 12 ounces per square yard, and exceeding 12 inches but not exceeding 24 inches in width, 55 per centum ad valorem. Woven fabrics, such as are commonly used for paddings or interlinings in clothing, composed wholly or in chief value of flax, or hemp, or of which these substances or either of them is the component material of chief value, exceeding 30 and not exceeding 110 threads to the square inch, counting the warp and filling, and weighing not less than 4½ and not more than 12 ounces per square yard, 55 per centum ad valorem; composed wholly or in chief value of jute, exceeding 30 threads to the square inch, counting the warp and filling, and weighing not less than 4½ ounces and not more than 12 ounces per square yard, 50 per centum ad valorem.

Paragraph 1010. Woven fabrics, not including articles finished or unfinished, of flax, hemp, ramie, or other vegetable fiber except cotton, or of which these substances or any of them is the component material of chief value, not specially provided for, 40 per centum ad valorem.

Paragraph 1011. Plain-woven fabrics, not including articles finished or unfinished, of flax, hemp, ramie, or other vegetable fiber, except cotton, weighing less than 4½ ounces per square yard, 35 per centum ad valorem.

SUMMARY.

Both imports and domestic production of hemp or ramie fabrics are negligible, therefore the fabrics to be considered are almost entirely those of flax.

The United States is the world's largest user of flax fabrics, but depends upon imports to supply the bulk of its requirements. The domestic production is comparatively small and confined mainly to coarse-yarn fabrics, particularly crashes, and a small output of goods, such as tailors' paddings, made from somewhat finer yarns.

Imports consist chiefly of lightweight fabrics, woven of fine yarn and usually highly finished, smaller quantities of tailors' paddings, and still smaller quantities of very heavy fabrics, such as canvas and sailcloth. Neither the very light nor the very heavy fabrics is produced in the United States and the domestic production of tailors' paddings dates only from 1915.

Ireland is the world's largest producer of linen fabrics, specializing in the production of the finer qualities. Imports into the United States originate principally in Ireland and Scotland, with smaller quantities coming from Belgium, France, and other countries.

Flax, hemp, and ramie are bast fibers, those obtained from the stalks and stems of the plant. Because of the similarity of these three fibers and the fact that they are practically interchangeable, fabrics made therefrom have received the same tariff treatment since 1897.

The term "hemp" as here used refers to the true soft hemp (*Cannabis sativa*), and does not include manila or other fibers which are sometimes, though incorrectly, listed under this heading.

The domestic production of woven fabrics of flax, hemp, or ramie is practically restricted to crash, huck toweling, tailors' paddings, and glass checks. While this entire production encounters foreign competition, such goods constitute a minor part of imports and are mainly dutiable at 55 per cent ad valorem, whereas the major part of imports, consisting of the lighter weight and more closely woven fabrics, are not manufactured in the United States and are dutiable at either 40 per cent ad valorem under paragraph 1010 or at 35 per cent ad valorem under paragraph 1011.

A wider range of medium-grade fabrics, as well as some coarse, heavy fabrics, can be produced in domestic mills without changing equipment. By employing broader looms a still wider range of fabrics can be produced. There is no apparent reason why the domestic linen industry can not manufacture, with the use of broad looms of domestic make, such goods as dress and suiting linen, embroidery linen, canvas, sailcloth, and certain grades of table damask. As linen fabrics increase in fineness of weave, they are usually more highly bleached and finished. Skilled operatives are essential for satisfactory results in manufacturing high-grade linens, and such operatives are not available in the United States.

In linen of fine quality, labor costs constitute a greater proportion of the total cost than is the case with the lower quality goods. Thus, owing to lower wage rates in Europe, the domestic producer would find keener competition in the finer qualities. Manufacturing costs also increase with the quality of the product much more rapidly in the case of linen than in the case of cotton goods, which means that the advantage of cotton goods in competing with linen for the market grows greater as the quality of the fabric becomes finer.

Since imported goods comparable to domestic products are dutiable under paragraph 1009 and imports of other goods are dutiable under paragraph 1010 or 1011, this report will treat competitive fabrics in one group and noncompetitive fabrics in another.

General Information.

DESCRIPTION AND USES.

COMPETITIVE FABRICS.

Fabrics falling in this class are chiefly crashes or the relatively coarse linens. They constitute the bulk of the domestic production of linen fabrics.

With the exception of a small amount of huck toweling, imports under this group are plain-woven fabrics.

(A) *Crashes.*—Crashes are coarse, plain-woven union or linen fabrics. The finer grades are used, to a limited extent, for dress linens, suits, and embroidery linen. The chief use, however, is for

dish toweling. Crashes intended for purposes other than for toweling are made in wider widths than the toweling crash. Wide looms, of which there are few in the domestic linen industry, are required to weave such fabrics.

Crashes for toweling form all but a small percentage of the domestic production of linen fabrics. In width they range from 12½ to 20½ inches and in weight from 5 to 8 ounces to the square yard. The range in thread count is from 37 to 75 threads per square inch, the bulk having about 50 threads. Crashes are sold either unbleached or bleached. As a rule they have a red or blue border.

On the basis of materials used, crashes fall into three groups, with the domestic production about equally divided among the three: (1) All-linen crashes, which constitute about three-fourths of those imported; (2) union crashes, in which the warp is pure cotton and the filling pure flax; and (3) mixed-yarn crashes, which are peculiarly a domestic product. In these mixed-yarn crashes the yarn is a mixture of flax noils (the waste from carding flax tow) and cotton spun together, so that neither the warp nor the weft is distinctly flax or cotton. The cotton content, however, usually exceeds the flax in weight.

Embroidery linens resemble crashes, but are usually starched and are woven of finer yarns.

A number of different types of linens are used for embroidery purposes, such as shrunk embroidery linens, white art linens, and brown embroidery linens. These range in width from 18 to 54 inches. The majority have less than 70 threads to the square inch and weigh less than 12 ounces per square yard. Embroidery linens, when ornamented, are used for table covers and runners.

(B) *Glass cloths.*—Glass cloths, or glass checks, are used for drying glasses. The domestic production is limited to one company, which has produced them only on a small scale. Glass cloths have a smooth glazed surface, and are usually divided into squares by the intersection of red or blue threads. They run in width from 16 to 24 inches; in threads to the square inch, from 60 to 80; and in weight per square yard, from 4½ to 6½ ounces.

(C) *Toweling, huck.*—Most of the toweling produced and consumed in the United States is below 100 per square inch in thread count and from 5 to 7 ounces per square yard in weight. This is the coarser-grade fabric; the finer grade, which contains as high as 200 threads to the square inch, is not generally made in the United States.

(D) *Tailors' paddings.*—Paddings, or interlinings, are stiffening material inserted in wearing apparel between the outer cloth and the lining in order that the garment may keep its proper shape. A linear yard of 22 or 24 inch material is required for the two fronts of a coat. Linen paddings, which are firm but flexible, are the most popular type of padding, forming, prior to the war, as much as three-fourths of the total domestic consumption. All-jute paddings, which are the cheapest and coarsest made, constitute the bulk of the remainder.[1] A marked increase since 1914 in the price of linen paddings has given a decided impetus to the manufacture of all-jute and union paddings, these latter composed mostly of flax and jute or

[1] See commission's survey on Jute Cloths, J-7, p. 34.

55033—J-8—23——2

of jute and cotton. The production of paddings marks a step forward in the development of the domestic linen industry. As compared with crashes, paddings are woven from finer yarns, have more threads to the square inch, and a more elaborate finish. Flax paddings are distinguished from the general run of linen fabrics by a starched and glazed appearance. This results from their being subjected to a sizing process by which the yarns are permeated with a substance, partially waterproofing the fabric, and causing it to resist the softening influence of moisture in the processes of cleaning and pressing or in rainy weather. They are plain-woven, unbleached fabrics 22 or 24 inches in width.

Paddings range in weight from about 5 to 10 ounces per square yard and in thread count from about 40 to 100 threads to the square inch; when made for special purposes these limits are occasionally exceeded. Those made of flax run to only 7.5 ounces per square yard in weight and not lower than 60 in thread count.

An analysis of 21 representative paddings manufactured in Ireland and Belgium gives the average yarn count used in both warp and weft as 23.7 lea. The actual yarn used, however, was probably a little below this number, because the samples analyzed had been sized and consequently the yarn was heavier than that actually spun. As a rule the warp and filling yarns were within 1 or 2 lea of each other.

NONCOMPETITIVE FABRICS.

(A) *Cambrics and sheers.*—These fabrics are imported for manufacture into handkerchiefs. They are finely woven and highly bleached. The predominating width is 36 inches. In weight they range from 1½ to 3 ounces per square yard and in thread count from 100 to 400 threads to the square inch, with those from 100 to 200 threads forming the bulk of the domestic consumption. The yarns employed run in lea from 90 to 160 in warp and from 120 to 190 in weft. The finest yarn spun commercially in the United States rarely exceeds 40 lea.

(B) *Dress and suiting linens.*—Suitings for women's dresses and men's suits are imported white or colored. A considerable part consists of colored crash 36 inches wide with about 50 threads to the square inch.

(C) *Blouse and waist linens.*—These fabrics are imported in a wide variety. They range from about 100 to 200 in threads per square inch.

(D) *Household linens.*—Imports of these fabrics are chiefly for further manufacture into sheets, pillowcases, and furniture coverings or slips.

Imports of linen sheeting and tubular linens for pillowcases form an insignificant part of the total imports of linen goods. Sheetings are usually woven in widths of 72 to 90 inches. In weight they range from about 4 to 4½ ounces per square yard and in thread count from about 100 to 160 to the square inch. Tubular linens for pillowcases have about the same thread count and weight as sheetings.

The small amount of furniture covering imported is mainly coutil—a strong twill cloth with herringbone stripes.

(E) *Heavy fabrics.*—The domestic consumption of heavy fabrics for [illegible]th, tarpaulin, etc., is the smallest of any of the types described. [illegible]due chiefly to the extensive use of domestic cotton duck.

Sailcloth represents all but a small part of the heavy linens consumed. This is used chiefly in the construction, maintenance, and repair of foreign vessels. It is usually woven in 24-inch widths with about 14 to 48 ends of ply yarn in the warp and from 12 to 36 single threads in the weft.

Tarpaulins are usually imported ready for use. The small amount imported in the untreated state for waterproofing in domestic mills comes in 41-inch widths.

(F) *Figured fabrics.*—Figured linen fabrics consist chiefly of table damask, huck toweling, and diaper cloth.

Small quantities of huck toweling are imported. That which competes with the domestic product is mentioned under "Competitive linens." The remainder, that which exceeds 100 threads to the square inch, is noncompetitive and pays a lower rate of duty; it ranges from 15 to 20 inches in width, contains from 100 to 200 threads to the square inch, and weighs from 5¼ to 7½ ounces per square yard.

Diaper cloth is usually woven with a filling yarn which is soft and coarse, as compared to the warp. This, combined with the filling-face weave (generally only one end out of four being up on each pick), makes a very soft-faced cloth. The cloth is further softened by the finishing processes—treating with an alkaline solution of caustic soda, bleaching, washing, and drying. Diaper cloth of vegetable fiber other than cotton is not in general use in the United States; it is not produced in domestic mills and imports are small.

Table damask is discussed in Section III.

TARIFF HISTORY.

In the act of 1883 fabrics of flax, hemp, or ramie were provided for on the basis of grade or quality, viz, brown and bleached linens, ducks, canvas, paddings, cot bottoms, diapers, crash, huckabacks, lawns, and Russia and other sheetings, brown or white, 35 per cent ad valorem; sail duck, or canvas for sails, 30 per cent ad valorem; other manufactures, including manufactures of ramie, 35 per cent ad valorem.

This method of classification was followed in some subsequent acts but not in others. Thus in the act of 1890 fabrics of flax or hemp containing 100 or less threads per square inch were dutiable at 50 per cent ad valorem, while fabrics of flax containing more than 100 threads to the square inch were dutiable at 35 per cent ad valorem, and fabrics of hemp or ramie containing more than 100 threads to the square inch were dutiable at 2 cents per pound when valued at 5 cents per pound or less and at 40 per cent ad valorem when valued above 5 cents per pound.

In the act of 1894 all flax, hemp, or ramie fabrics, regardless of construction or quality, fell under general provisions at 35 per cent ad valorem.

In the act of 1897 all fabrics of flax, hemp, or ramie weighing not less than 4½ ounces per square yard were dutiable at not less than 50 per cent ad valorem. This minimum rate of 50 per cent applied when the compound rates did not amount to an equivalent ad valorem rate of 50 per cent. The compound rates were on a graduated basis and ranged from 1¾ cents per square yard plus 30 per cent ad valorem on fabrics weighing 4½ ounces or more per square yard and containing not more than 60 threads per square

inch to 9 cents per square yard plus 30 per cent ad valorem on fabrics weighing 4½ ounces or more per square yard and containing more than 180 threads per square inch. Fabrics weighing less than 4½ ounces per square yard and containing more than 100 threads to the square inch were dutiable at 35 per cent ad valorem, and fabrics weighing less than 4½ ounces per square yard and containing 100 or less threads per square inch were dutiable under a general provision at 45 per cent ad valorem.

The provisions of the act of 1909 with respect to flax, hemp, or ramie fabrics were the same as those in the act of 1897, except that the act of 1909 provided separately for fabrics weighing less than 4½ ounces per square yard and containing 100 or less threads per square inch, while the act of 1897 did not provide separately for such fabrics.

The act of 1913 provided for all plain-woven fabrics of flax, hemp, or ramie, at 30 per cent ad valorem; fabrics other than plain-woven falling under a general provision at 35 per cent ad valorem.

In the act of 1922 the basis employed is again that of construction—threads per square inch, weight per square yard, and width. The duties range from 35 to 55 per cent ad valorem, the higher rates applying to such fabrics as are comparable with the domestic product, or the medium grade fabrics, while the lower rates apply to the non-competitive fabrics, or those which are either very heavy, such as sailcloth, or those which are of light weight, such as cambric, neither of which grades is produced in the United States.

Prior to the act of 1922 paddings had never been specially provided for; they had been dutiable along with other fabrics of flax or hemp. They are specially provided for in the act of 1922 because the provisions applying to other competitive fabrics are not broad enough to cover the range in paddings.

DOMESTIC PRODUCTION.

The output of the domestic linen industry consists of woven goods, thread, twine, and yarns. Comparatively small quantities of yarn are produced for sale, as most of it is consumed in the mills where spun, in the production of fabric, thread, and twine.

Statistics concerning domestic production show that in 1899 there were 18 establishments engaged primarily in the production of linen goods. In addition to thread, twine, and yarn, these produced in 1899 nearly 7,000,000 square yards of woven goods, valued at $796,000. In 1909 there were 15 establishments similarly engaged and their production of woven goods was nearly 10,500,000 square yards, valued at $1,575,000. In 1914 there were 21 establishments producing linen goods and the output of woven goods was 10,799,628 square yards, valued at $1,765,798, while in 1919 the number of establishments decreased to 10 and the output of woven goods increased to 14,342,000 square yards, valued at $3,799,000. In the census year 1921 the output of the 13 establishments constituting the domestic linen industry was 8,945,000 square yards, valued at $3,537,000. A comparison of the value of the production of woven goods with the value of other products of the industry shows that woven goods constituted 18 per cent of the total value of all products in 1899, 25 per cent in 1909 and in 1914, 54 per cent in 1919, and 48 per cent in 1921.

The fluctuations in the number of wage earners and in wages paid in the linen industry for the census years 1899 to 1914 were very slight, notwithstanding the changes in the number of establishments. Wage earners in the industry as a whole averaged 3,566 in number, and total wages averaged $1,240,197 in these census years. In 1919 the number of establishments was 10 as compared with 21 in 1914, and the number of wage earners was 1,890 as compared with 3,567; total wage payments increased from $1,386,117 in 1914 to $1,635,042 in 1919.

The large decrease in the number of establishments and in the number of employees between the census years 1914 and 1919, coincident with an increase in the production of woven goods, is explained by the fact that the establishments which were producing woven goods in 1914 were still operating in 1919, while the establishments which were producing flax twine in 1914 had, owing to the scarcity and high price of flax, turned to other raw materials in 1919 and were not included in the linen industry. In substantiation of this deduction the quantity of flax twine produced may be cited, decreasing from 3,953,622 pounds in 1914 to 84,415 pounds in 1919.

Massachusetts, with three establishments, produced 48½ per cent of the total value of all products in 1921, and is the leading State in the linen industry. There were two establishments each in Minnesota, New Hampshire, New Jersey, and New York, and one each in Pennsylvania and Wisconsin.

The output in 1921 of the 13 establishments was about 50 per cent of the maximum capacity, based upon a demand requiring full-time operation.[2]

No tailors' paddings were produced in the United States prior to 1915, in which year one company began producing them. Three companies were making paddings in 1918, but since 1921 only one company has been manufacturing this product. According to information from independent sources, the three companies produced 8,540,000 linear yards of padding in 1918, 4,200,000 linear yards in 1919, and 4,150,000 linear yards in 1920. The product of the one company manufacturing paddings in 1921 and 1922 consisted largely of jute and cotton paddings, although some all-flax and some flax and jute paddings were made. It should be noted that the production of flax padding is included in the general statistics of production for the linen industry as a whole, page 25.

IMPORTS FOR CONSUMPTION.

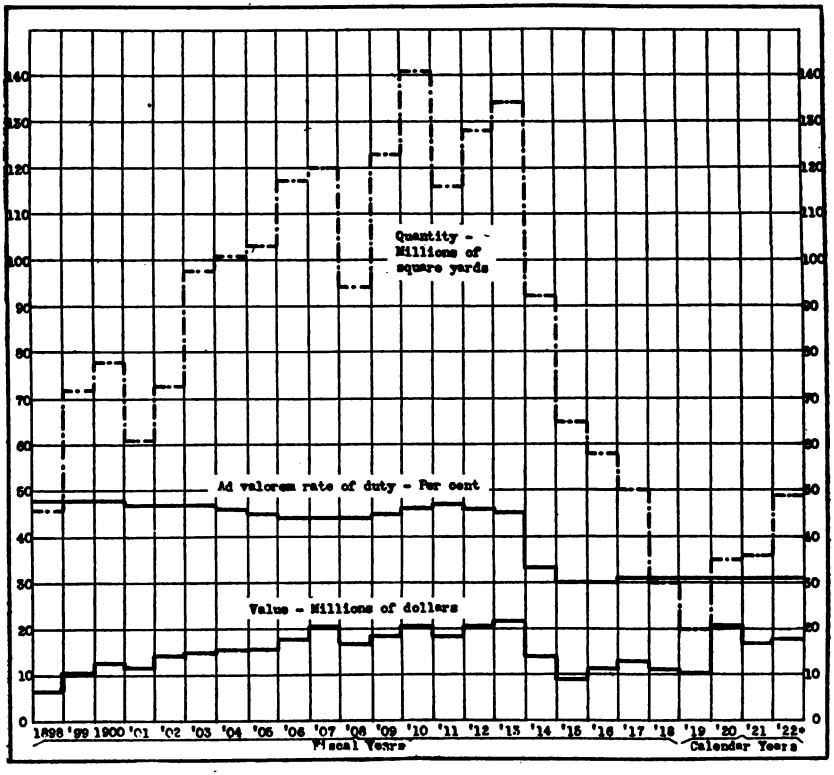
During the periods 1910–1913, inclusive, and 1917–1922, inclusive, imports of woven fabrics of flax, hemp, or ramie were recorded in detail, while in all other years since 1898 some classes of fabrics were not specially provided for and were entered with general manufactures. Thus during the period 1898–1902, inclusive, neither the quantity of fabrics on which the ordinary duty did not amount to 50 per cent, nor the quantity or value of fabrics weighing less than 4½ ounces per square yard and containing not more than 100 threads to the square inch, was separately recorded. During the period 1903–1909, inclusive, fabrics weighing less than 4½ ounces per square

[2] United States census of manufactures, 1921.

yard and containing not more than 100 threads to the square inch were still not shown separately, although the quantity of imports of fabrics on which the ordinary duty did not amount to 50 per cent was shown. During the period October 3, 1913, to June 30, 1916, fabrics other than plain woven were not shown separately in import statistics, although such imports have been separately recorded since June 30, 1916.

The following chart shows the quantity and value of imports as well as the ad valorem equivalent rates of duty during the years 1898–1922, inclusive. It should be kept in mind that, as noted above, during the periods 1898–1909, inclusive, and 1914–1916, inclusive, certain fabrics are not included.

Woven fabrics of flax, hemp, or ramie—Imports for consumption, 1898 to 1921, showing quantity, value, and average ad valorem rate of duty.



Quantity - Millions of square yards
Ad valorem rate of duty - Per cent
Value - Millions of dollars

Fiscal Years
Calendar Years

* Jan. 1, to Sept. 21, 1922.

Linen goods imported into the United States originate chiefly in the United Kingdom, less than 1 per cent in 1919, about 8 per cent in 1920, and 12 per cent in 1921 having come from all other countries combined. Ireland sends the finer, highly bleached fabrics, while the coarser goods come largely from Scotland.

According to British statistics, approximately 90 per cent of the linen piece goods exported from the United Kingdom to the United States during the period 1906 to 1921, inclusive, was plain goods—

about one-half of which was bleached and one-half unbleached. The remaining 10 per cent was made up of "checked, printed, and dyed" goods, and "damask and diaper" cloth. Plain goods consist of certain household linens, such as sheeting, pillow linen, crash toweling, and similar goods, while "checked, printed, and dyed" refers to such goods as dress linens and glass cloths, and "damask and diaper" consists chiefly of table damask.

Imports for consumption during the fiscal years 1910–1913 averaged 129,944,365 square yards in quantity and $20,227,723 in value; duties averaged $9,279,379. Imports in the fiscal year 1910 amounted to 141,489,520 square yards, valued at $20,828,848, yielding a revenue of $9,587,324, or 46.03 per cent of the value. Although imports held up well until 1913, they were below those of 1910, and after 1913 they steadily declined through the war period, and amounted to only 20,882,537 square yards, valued at $10,591,592 in 1919. In 1920 imports were 35,694,760 square yards, valued at $21,365,194. They increased to 36,594,557 square yards, valued at $17,005,531 in 1921, and during the period January 1 to September 21, 1922, they amounted to 49,262,126 square yards, valued at $17,932,861. Owing to the great increase in prices, imports in 1920, while constituting only 27 per cent of the quantity, actually exceeded by 5.6 per cent the average value of imports during the fiscal years 1910–1913. As indicating the extent to which prices have held to the high level, imports during the period January 1 to September 21, 1922, were 38 per cent in quantity and 89 per cent in value of the average during the fiscal years 1910–1913.

Imports under paragraph 1109 in the act of 1922 will represent very closely the range of fabrics made in domestic mills, and will, therefore provide, for the first time, a basis for a comparison of imports with domestic production.

Paddings are imported in a great variety of qualities, but as no separate record of such imports has been kept, they have been included with other fabrics. Inasmuch as they are specially provided for in the act of 1922, imports have been separately recorded since September, 1922. The bulk of imports consists of all-linen paddings, although all-jute, jute and cotton, and flax and jute paddings are also imported. Imports originate chiefly in Ireland and Scotland, Ireland specializing in all-linen paddings and Scotland in those of jute and cotton. Belgium is also an important source of imports.

The domestic consumption of paddings is estimated at about 50,000,000 linear yards per year.

EXPORTS.

FROM THE UNITED STATES.

Exports of woven fabrics of flax, hemp, or ramie from the United States are not separately stated in export statistics, but are known to be negligible.

FROM THE UNITED KINGDOM.

Prior to 1914 all manufactures of linen exported from the United Kingdom were grouped in British statistics under the classification "linen manufactures, unenumerated." In 1914 separate classifi-

cations were established for "table linen, not in the piece," and "handkerchiefs, not in the piece." Since 1914 tablecloths and napkins have constituted on an average approximately one-half of the value of total exports of all manufactures of linen, with the exception of yarn and thread for sewing, from the United Kingdom to the United States; handkerchiefs have constituted about one-third, and the remainder, or one-sixth, has been made up of miscellaneous manufactures, such as lace and embroidery, rick covers, tarpaulin, tents and awnings, buckets, etc.

The United States is the United Kingdom's best customer for linen piece goods. Thus in only three of the calendar years from 1906 to 1921, inclusive, did the United States fail to take as much as one-half of the United Kingdom's total exports of such goods (38 per cent in 1918, 29.9 per cent in 1919, and 48.3 per cent in 1920). South America is the United Kingdom's next best customer for this class of merchandise.

The United Kingdom has also found its best market for manufactures of linen, such as handkerchiefs, tablecloths, napkins, etc., in the United States. In only four of the calendar years, from 1909 to 1921, inclusive, did the value of such exports destined for the United States fall below 50 per cent of the total (46.7 per cent in 1911, 44.1 per cent in 1912, 42.7 per cent in 1913, and 37.2 per cent in 1919), while in 1921 the value of such exports shipped to the United States was over three-fourths of the total.

In addition to exports from the United Kingdom to foreign countries, considerable quantities of both linen piece goods and manufactures of linen are sent into British possessions. This trade with the colonies in piece goods amounts on an average to approximately one-quarter of the trade with foreign countries, except for sailcloth, in which it slightly exceeds that with foreign countries. The trade in manufactures of linen (handkerchiefs, tablecloths, napkins, etc.) is divided fairly evenly between British possessions and foreign countries.

DOMESTIC CONSUMPTION.

Considered from the standpoint of total domestic consumption (domestic production plus imports) of all kinds of linen fabrics, about 90 per cent of the domestic demand was met by imports in the census years 1899, 1909, and 1914. In 1919 domestic production was one and one-third times in quantity and almost two and one-fourth times in value the production in 1914. In the meantime imports had dropped by almost 75 per cent. Thus imports supplied but 46.6 per cent of domestic consumption in 1919 as compared with 90 per cent during the pre-war period. Comparing 1921 with 1919, however, domestic production decreased by about one-third, or to about 50 per cent of the maximum capacity of domestic mills, while imports more than doubled. This means that about 75 per cent of the domestic consumption in 1921 was supplied by imports. The products of the linen industry are not numbered among the necessities of life, therefore economic factors, such as the price relationship to products which are available as substitutes, determine the consumption by the users thereof.

PRICES.

The net wholesale selling price, on the American market, of eight different grades of Scotch linen crash averaged 17.4 cents per linear yard in September, 1921, as compared with 17.8 cents per linear yard for 12 different grades of domestic crash in May of the same year. The Scotch crash averaged 17.7 inches in width, 51 threads per square inch, and 7.7 ounces per square yard, while the domestic crash averaged 17.9 inches in width, 49 threads per square inch, and 4.7 ounces per square yard. The net invoice price of the Scotch crash increased from 5.7 cents to 18.1 cents per linear yard between March, 1914, and May, 1920. The net wholesale selling price of the domestic crash increased to about the same extent, or somewhat more than 200 per cent. In the latter months of 1922 prices of both the Scotch and the domestic crash were about 100 per cent above the 1914 prices.

The difference between the invoice price and the wholesale selling price of the Scotch crash averaged approximately 6.3 cents per linear yard in the latter part of 1921; this is a spread of somewhat more than 50 per cent. After paying the duty (30 per cent ad valorem) about 20 per cent remained to cover landing charges, overhead, and profit.

Prices of other woven fabrics of flax, hemp, or ramie included in this section increased between 1914 and the peak price of 1920, from 200 to 400 per cent, while in 1922 they decreased to a point from about 100 to 200 per cent above 1914 prices.

WAGES.

Data concerning wages in the foreign linen industry are meager, but the wage scale in the domestic industry, although the product does not include the higher grade goods, is decidedly higher. This condition is not peculiar to the linen industry. The difference is greater in the linen industry, however, because lower wages are paid in that industry than in any other textile industry of the United Kingdom. The American linen mills do not differ materially with respect to their wage scales from other domestic textile industries.

It should be noted also that as the products of the linen industry increase in fineness of weave and completeness of bleach the ratio of labor cost to total cost tends to increase proportionately. Thus, should the domestic industry attempt the production of light-weight, highly bleached linens the element of labor cost would be a deterring factor.

It is possible, of course, for the difference in efficiency of operation to offset, in a measure, the differences in costs of production between domestic and foreign mills.

METHODS OF PRODUCTION.

Yarn spinning.—With the exception of 15 per cent, the yarn requirements of the domestic linen industry are supplied by domestic producers. The yarn is spun from imported fiber, there being but small quantities of fiber produced in the United States, and such as

55033—J-8—23——3

is produced is not popular with spinners. Some domestic mills spin their yarn while a few weave only, buying the yarn largely in foreign markets. There are no domestic mills which confine their operations to spinning for sale; the mills use most of the yarn spun in further manufacture, either in weaving or in making thread, twine, and cord; consequently very little yarn of domestic manufacture is available for the weaving mills which do not have their own spinning department. One domestic mill has 1,000 spindles but has never spun yarn; the spindles merely guard against conditions under which yarn from regular sources of supply might not be available.

Weaving.—The operations involved in weaving linen goods do not differ widely from those employed in weaving cotton goods, and the looms used are practically all made in this country. Both plain and automatic looms are used, the former predominating.

Bleaching and finishing.—The bleaching and finishing of linen fabrics are processes exceedingly difficult, as compared with similar operations for cotton fabrics, owing to the greater amount of extraneous matter in the linen fiber. Domestic bleaching of linen goods is not carried through to the same degree of perfection as that practiced abroad for fine linens. Domestic crashes are generally boiled and bleached in the piece. They are first boiled in a strong alkaline solution and then, after washing, are steeped in a weak solution of hydrochloric acid, which neutralizes the alkali. They are then washed and dried by passing over heated cylinders. Bleaching of fine linens, as carried on in Ireland, requires from six to eight weeks of washing, boiling, and spreading the fabric on the grass. Grass bleaching accounts for the whiteness and softness of Irish linens. In addition to skilled workers, who are unexcelled, Ireland enjoys certain climatic conditions which are decidedly advantageous to the production of fine linen. For instance, grass bleaching could not be accomplished in the United States, because long periods of uniformly temperate and moist atmospheric conditions must prevail. Linens from the Continent are sent to Ulster for bleaching, dyeing, and finishing. Only a small part of the world's consumption of linen is grass-bleached; the bulk is bleached entirely by chemicals.

A large proportion of flax yarn is boiled or bleached before going to the loom. Boiling removes dirt and impurities and makes a tighter and firmer cloth. Yarns intended for use in the manufacture of fine, white linens, pillow linen, sheeting, and damask are usually boiled. As a rule yarns that are bleached are those intended for glass cloth, damask, huckaback, and towels, which are not bleached after weaving. Some fabrics, however, are bleached both in the yarn and in the piece.

Mill construction.—Since most of the machinery used in the manufacture of linen goods is very heavy, linen mills must be strongly built. This, together with the high price of machinery used in a linen mill as compared with that used in a cotton mill, means that a linen mill costs several times as much per spindle as a cotton mill

COMPETITIVE CONDITIONS.

The domestic linen industry has not developed beyond the production of a few medium-grade fabrics, but is fairly well established. There are certain natural obstacles as well as inherent difficulties operating against its development.

The domestic production of flax fiber is small and it is pronounced by spinners as unsatisfactory for their use. Therefore, imported fiber is used by domestic spinners in the production of yarns for use in weaving.

There are no domestic mills which confine their operations to spinning yarn. The bulk of yarn spun in domestic mills is consumed in the same mills in further manufacture. Consequently domestic weaving mills which have no spinning department, or which can not spin sufficient yarn for their requirements, must depend largely upon foreign sources for all or part of their yarn. The duty on imported yarn ranges from 25 per cent ad valorem to 35 per cent ad valorem, according to the count or size.

Except for the looms, machinery for the equipment of a linen mill must be imported, as it is not made in the United States, and must pay, in addition to a price, which is very high compared to similar machinery for a cotton mill, a duty of 35 per cent ad valorem.

Bleaching and finishing cotton goods, as well as the domestic output of linen goods, require only a few hours, or days at the outside, while a part of the high-grade linens produced in Ireland attain their whiteness and softness by elaborate processes requiring from six to eight weeks of treatment.

The domestic output of linen fabrics, being of medium grade, does not require the highly skilled operatives necessary in the manufacture of the finely-woven, light-weight goods, although the operations are somewhat more difficult than those employed in the manufacture of similar cotton goods.

These natural difficulties attending the production of other than medium grade linen fabrics operate to restrict the development of the domestic linen industry, but the range of goods falling in the medium grade class includes some fabrics which are not, but obviously could be, made in domestic mills. Dress and suiting linen, embroidery linen, and table damask, for instance, could be made by domestic manufacturers, with the use of broader looms than those now employed.

Imports, while made up largely of noncompetitive goods, also include goods which compete with the domestic product. The domestic product has, however, shown a substantial increase in quantity, having been, in 1919, over twice the output of 1899, although in 1921 it was only about one-third greater than in 1899.

While the domestic linen industry encounters competition from imports, there is another and quite important element. It is competition with cotton goods, and affects imports as well as domestic production. Cotton goods, being cheaper, compete with linens by "displacement." This "displacement," or substitution of cotton goods for linens, occurs when the difference in price reaches the point where the use of cotton becomes more economical. In the case of toweling crash this "displacement" form of competition is not as pronounced as it is in the case of the higher grade fabrics, because the cost of production of linens increases with the fineness of weave and completeness of bleach much more rapidly than in the case of cotton goods. If linen table damask were available at the same price as cotton table damask it is extremely doubtful if any cotton damask would be used. On the other hand, there are certain users of fine linen goods in the United States who will continue to use linen irrespective of the price differential in favor of a cotton substitute.

The price relationship in January, 1923, of linen and cotton goods which might be put to the same uses was as follows:[1]

	Lawn, 36 inches wide, per yard.	Toweling, 17 inches wide, per yard.	Damask tablecloths, 69 by 69 inches, per cloth.	Damask napkins, 20 by 20 inches, per dozen.
Linen	$1.50	$0.30	$3.80	$5.00
Cotton	.35	.15	1.90	2.75
Ratio of linen price to cotton price (per cent)	428	200	200	182

SECTION II.

PILE FABRICS OF VEGETABLE FIBER OTHER THAN COTTON, AND MANUFACTURES THEREOF.

TARIFF ACT OF 1922.

Paragraph 1012. Pile fabrics, composed wholly or in chief value of vegetable fiber other than cotton, cut or uncut, whether or not the pile covers the whole surface, and manufactures in any form, made or cut from any of the foregoing, 45 per centum ad valorem.

GENERAL INFORMATION.

DESCRIPTION AND USES.

A pile fabric is one consisting of a foundation cloth covered entirely or partly by short projecting ends or loops formed by an extra set of threads. In a flax pile fabric the ground threads are usually of cotton and the pile is formed from flax threads. The cotton ground gives greater flexibility. Pile fabrics made of vegetable fiber other than cotton are lacking somewhat in resiliency; the pile does not revert so rapidly to an upright position after having been pressed down. For this reason flax, hemp, and ramie are not generally used in the manufacture of pile fabrics, such fabrics of these materials are used principally for furniture coverings and are a specialty production, showing cut or uncut pile figures on a loose (nonpile) ground. All-over pile fabrics made from vegetable fiber other than cotton are used principally for portières and hangings.

The commonest pile fabric is turkish towels, of which imports are small. Most are imported on special order and are dutiable under paragraph 1114.

TARIFF HISTORY.

Pile fabrics of flax were separately provided for the first time in the tariff act of 1913. Prior to that act such fabrics, as well as manufactures of pile fabrics, had fallen under the general provisions for manufactures. Pile fabrics of hemp or ramie, as well as manufactures thereof, were dutiable under general provisions for manufactures until 1913 when hemp and ramie were mentioned along with flax as component materials. The act of 1922 provides for pile fabrics and manufactures made therefrom, composed wholly or in chief value of vegetable fiber other than cotton, at 45 per cent ad

[1] Prices quoted by a large department store in Washington.

valorem. Under the act of 1913 the rate was 40 per cent ad valorem on flax, hemp, or ramie fabrics and manufactures, while the act of 1909 imposed a rate of 60 per cent ad valorem on fabrics and manufactures of flax and 45 per cent ad valorem on fabrics and manufactures of hemp or ramie.

DOMESTIC PRODUCTION.

There are no separate records of domestic production of pile fabrics, but it is negligible.

IMPORTS.

Prior to the war the value of imports of pile fabrics of flax, hemp, or ramie ranged around $200,000 per year, attaining a peak of $235,628 in 1913. Imports declined rapidly during the war period, being valued at only $3,603 in 1918. Since 1918 imports have increased gradually, but in 1922 they were less than half of pre-war imports.

Beginning in 1919 imports were recorded by quantity. The value per square yard increased from 46 cents in 1919 to $1.82 in 1921 and then declined to $1.27 in 1922.

Imports originate mainly in France and Germany.

Imports of manufactures of pile fabrics were first separately stated in 1910. Since that time they have been less than $5,000 in value in each year except 1921 and 1922, when the value was $29,390 and $7,475, respectively.

EXPORTS.

There are no exports of pile fabrics of flax, hemp, or ramie, or of manufactures of such fabrics.

SECTION III.

TABLE DAMASK OF VEGETABLE FIBER OTHER THAN COTTON, AND MANUFACTURES THEREOF.

TARIFF ACT OF 1922.

Paragraph 1013. Table damask composed wholly or in chief value of vegetable fiber other than cotton, and manufactures composed wholly or in chief value of such damask, 40 per centum ad valorem.

GENERAL INFORMATION.

DESCRIPTION AND USES.

Damask is a woven figured fabric distinguished by the appearance of the design on the smooth surface without any contrast in colors. The surface threads in the figures lie at right angles to those in the ground, with the result that the light falling on the smooth surface is refracted as it strikes the figures and the pattern stands out in relief.

Damask made from vegetable fiber other than cotton is practically limited to linen damask. It ranges in width from 60 to 90 inches, in weight from 4 to 6 ounces per square yard, and in threads from 96 to 350 to the square inch.

55033—J-8—23——4

These goods, as the designation indicates, are used as dining-room table covers, napkins, tray cloths, etc.

A large amount of linen damask is imported in the piece and made up in domestic mills, although considerable quantities of cloths or napkins are also imported.

TARIFF HISTORY.

Table damask and manufactures made therefrom were specifically mentioned for the first time in the act of 1922. In previous acts the fabric in the piece was dutiable on the weight and thread-count standards, when such standards were prescribed, and manufactures made from this fabric, such as tablecloths and napkins, were dutiable under the general provisions for manufactures.

DOMESTIC PRODUCTION.

A small quantity of linen and of union damask is produced in domestic mills. The exact amount is not known.

IMPORTS.

Imports of table damask of vegetable fiber other than cotton have not been separately stated and neither the quantity nor the value is known. Practically all of such imports are of linen damask, largely from the United Kingdom. Belgium and Germany send some of these goods to the United States, as does France. A large part of those from France are embroidered.

EXPORTS.

There are no exports of table damask of vegetable fiber other than cotton.

COURT AND TREASURY DECISIONS.

Paragraph 346 of the act of 1897 was held not to be restricted to woven fabrics in the piece, and finished articles of flax such as linen doilies and tray cloths were held to fall within the scope of that provision. (McBratney *v.* United States, 105 Fed. 767, certiorari denied, 181 U. S. 621.) The words "foregoing articles" in the proviso of that paragraph were held to include woven fabrics as well as finished articles. (Schulman *v.* United States, 123 Fed. 1002.) So-called Roman canvas composed of flax and coated on one side with paint was held to be dutiable under the provision for woven fabrics in paragraph 346 rather than at a lower rate of duty as manufactures of flax and paint. (G. A. 4465; T. D. 21325.) Flax articles and fabrics weighing less than 4½ ounces per square yard and containing less than 100 threads per square inch were held not to be provided for in paragraph 346 and therefore to be relegated to the basket clause, paragraph 347. (G. A. 5238; T. D. 24084.)

The provision in paragraph 342 of the act of 1897 for "all pile fabrics of which flax is the component material of chief value" was held to be more specific as regards plush composed in chief value of

flax than the provision in paragraph 315 of that act for plush composed of cotton or other vegetable fiber. (Stern *v.* United States, 99 Fed. 417; Ryer *v.* United States, 126 Fed. 246.)

Card cloth in chief value of flax, known in the textile industry as a "plain double weave," woven double by an intricate and elaborate method for the purpose of increasing its weight and strength, but presenting by its weave a plain as distinguished from a figured or twilled effect, was held to be dutiable under the provisions of paragraph 283 of the act of 1913 as "plain woven fabrics" and not as "manufactures of flax" under paragraph 284. The test of whether or not a fabric is "plain woven" under paragraph 283 was held to be the appearance its weave presents and not the manner of its weaving. (Stone *v.* United States, 7 Ct. Cust. Appls. 365, of 1916.) Flax fabrics, with triple warp and double weft, not figured in any manner, having a perfectly plain appearance and the weave uniform throughout, were held to be plain woven and dutiable under paragraph 283. (Abstract 38771 of 1915, following 99 Fed. 262 of 1900; White *v.* United States, 2 Ct. Cust. Appls. 327 of 1911; and United States *v.* White, 3 Ct. Cust. Appls. 382 of 1912). Flax canvas with a double warp and a single weft, having a perfectly plain appearance and the weave uniform throughout, was likewise classified. (Abstract 39693, of 1916.)

Chain-bordered crash or crash toweling, so woven as to produce a distinctly discernible border the whole length of the piece, whether the border is in color or in plain white, although each weave if alone employed would result in a plain woven fabric, is figured and not plain woven, and was held to be dutiable as a manufacture of flax under paragraph 284 of the act of 1913. (United States *v.* White, 3 Ct. Cust. Appls. 382, of 1912; United States *v.* Douglas, 6 Ct. Cust. Appls. 100, of 1915, followed in Abstract 37996 of 1915, Abstract 39051 of 1916, and Abstracts 45645 and 45835 of 1923.) Bordered flax crash, however, where the weave is plain and the same in the border as in the body of the fabric, even though the border is colored, was held to be plain woven within paragraph 283 and dutiable thereunder. (Abstracts 37996 and 38772 of 1915.)

Huck toweling woven in such a manner that the weft threads appear at regular intervals in groups on the surface of the fabric, making a dotted or figured effect, is not a plain-woven fabric. (Abstract 35653, T. D. 34468 of 1914; followed in Abstract 37000, T. D. 34984 of 1914.) Neither is linen damask plain woven. (White *v.* United States, 2 Ct. Cust. Appls. 327 of 1911.)

Plain-woven flax fabrics under 12 inches in width were held to be dutiable at 30 per cent under paragraph 283 of the act of 1913 rather than at 25 per cent as fabrics with fast edges not exceeding 12 inches in width made of vegetable fiber under paragraph 262. (Abstract 37256 of 1915, followed in Abstract 38774 of 1915.)

Flax pillow tubing in 20 or 30 yard lengths was held to be a fabric rather than an article. (Abstract 34361 of 1913.) Flax scarfing with a hem and hemstitching was also held not to be an article, finished or unfinished, but to be advanced beyond the condition of a plain-woven fabric and dutiable as a manufacture of flax. (Lamb *v.* United States, 6 Ct. Cust. Appls. 115 of 1915.)

Towels of cotton and flax with a loop pile similar to terry cloth were held dutiable as pile fabrics in chief value of flax under paragraph 280 of the act of 1913 rather than as manufactures of flax under paragraph 284. (Abstract 44447 of 1921.)

A plain-woven fabric having a cotton warp and jute filling, jute being the component material of chief value, was held not to be within the provision for "plain-woven fabrics of jute yarn" in paragraph 408 of the free list but to be dutiable as a manufacture of vegetable fiber under paragraph 284. (G. A. 8124, T. D. 37492.)

Among the articles held dutiable under paragraph 284 of the act of 1913 are the following: Union towels in chief value of flax (Abstract 38815 of 1915); "hemp allover," a woven fabric of manila hemp, not plain woven (Abstract 41931 of 1918); chain-bordered crash or crash toweling, not plain woven (United States *v.* White, 3 Ct. Cust. Appls. 382 of 1912; United States *v.* Douglas, 6 Ct. Cust. Appls. 100 of 1915, followed in Abstract 37996 of 1915, Abstract 39051 of 1916, and Abstracts 45645 and 45835 of 1923); huck toweling, not plain woven (Abstract 35653, T. D. 34468 of 1914; Abstract 37000, T. D. 34984 of 1914); flax card cloth, twilled (Abstract 37354 of 1915, followed in Abstract 38037 of 1915); linen damask (White *v.* United States, 2 Ct. Cust. Appls. 327 of 1911); linen towels, having a zigzag pattern, woven at each end, with open-work effect (Abstract 38282 of 1915); hemstitched flax towels, with an additional row of spoke stitching or open work simulating hemstitching about 4 inches from the hem and commercially known as hemstitching (G. A. 8056, T. D. 37142 of 1917); unfinished flax articles consisting of woven pieces of linen with a staff design for embroidering with a very small part of the outline design filled in with embroidery thread (Abstracts 42153 of 1918, and 43017 of 1919); and tennis nets made from Russian hemp (G. A. 7745, T. D. 35562 of 1915).

[1] The sterling price is the foreign-mill price, while the currency price is the wholesale selling price in the United States. Sterling prices have been converted on the basis of exchange at par for the pre-war period; 80.1 per cent of par for October, 1921, 91.4 per cent of par for May, 1922; and 95.3 per cent of par for December, 1922.

[2] For description of goods see Table 3, p. 20.

[1] During the period 1898 to 1902, inclusive, the quantity of fabrics on which the ordinary duty did not amount to 50 per cent was not shown. During the period 1898–1909, inclusive, fabrics weighing less than 4½ ounces per square yard and containing not more than 100 threads to the square inch were not shown separately. During the period Oct. 3, 1912, to June 30, 1916, fabrics other than plain woven were not shown separately. See Tables 16, 17, and 18.
[2] July 1 to Dec. 31.
[3] Calendar year.

TABLE 16.—*Woven fabrics of flax, hemp, or ramie—Imports for consumption, 1898–1922.*

Percentage of total exported to United States	62.2	37.2	56.4	65.2

[3] Includes all other manufactures, except yarn, and thread for sewing.

Rates of duty on fabrics of flax, hemp, or ramie, 1883–1922.

Act of—	Paragraph.	Tariff classification or description.	Rate of duty.
1883	334	Brown and bleached linens, ducks, canvas, paddings, cot bottoms, diapers, crash, huckabacks, handkerchiefs, lawns, or other manufactures of flax * * * or hemp, or of which flax * * * or hemp shall be the component material of chief value not specially enumerated or provided for in this act.	35 per cent ad valorem.
	348	Sail duck, or canvas for sails	30 per cent ad valorem.
	349	Russia and other sheetings of flax, or hemp, brown or white	35 per cent ad valorem.
	350	All other manufactures of hemp * * * or of which hemp * * * shall be the component material of chief value, not specially enumerated or provided for in this act.	Do.
	351	* * * manufactures of * * * ramie * * * not specially enumerated or provided for in this act.	Do.
1890	371	All manufactures of flax or hemp, or of which these substances, or either of them, is the component material of chief value, not specially provided for in this act. *Provided*, That until January first, eighteen hundred and ninety-four [extended to January 1, 1895, by act of March 3, 1893, chap. 216, 26 Stat. 593] such manufactures of flax containing more than 100 threads to the square inch, counting both the warp and filling, shall be subject to a duty of 35 per cent ad valorem in lieu of the duty herein provided.	50 per cent ad valorem.
	374	All manufactures of * * * other vegetable fiber, except flax, hemp or cotton, or of which * * * other vegetable fiber, except flax, hemp or cotton, is the component material of chief value, not specially provided for in this act: Valued at 5 cents per pound or less Valued above 5 cents per pound	 2 cents per pound. 40 per cent ad valorem.
1894	277	All manufactures of flax, hemp, * * * or other vegetable fiber, except cotton, or of which these substances or either of them is the component material of chief value, not specially provided for in this act. (See proviso, par. 371, act of 1890.)	35 per cent ad valorem.
1897	342	All pile fabrics of which flax is the component material of chief value.	60 per cent ad valorem.

Rates of duty on fabrics of flax, hemp, or ramie, 1883–1922—Continued.

Act of—	Paragraph.	Tariff classification or description.	Rate of duty.
1897	346	Woven fabrics * * * not specially provided for in this act, composed of flax, hemp, or ramie, or of which these substances or either of them is the component material of chief value, weighing 4½ ounces or more per square yard:	
		Containing not more than 60 threads to the square inch, counting the warp and filling.	1¼ cents per square yard.
		Containing more than 60 and not more than 120 threads to the square inch.	2¼ cents per square yard.
		Containing more than 120 and not more than 180 threads to the square inch.	6 cents per square yard.
		Containing more than 180 threads to the square inch.....	9 cents per square yard
		And in addition thereto, on all the foregoing.....	30 per cent ad valorem.
		Provided, That none of the foregoing articles in this paragraph shall pay a less rate of duty than 50 per cent ad valorem.	
		Woven fabrics of flax, hemp, or ramie, or of which these substances or either of them is the component material of chief value, including such as is known as shirting cloth, weighing less than 4½ ounces per square yard, containing more than 100 threads to the square inch, counting the warp and filling.	35 per cent ad valorem.
	347	All manufactures of flax, hemp, or ramie, * * * or of which these substances, or either of them, is the component material of chief value, not specially provided for in this act.	45 per cent ad valorem.
1909	353	All pile fabrics, whether or not the pile covers the entire surface, composed of flax, or of which flax is the component material of chief value, and all articles and manufactures made from such fabrics, not specially provided for in this section.	60 per cent ad valorem.
	357	Woven fabrics * * * not specially provided for * * * composed of flax, hemp, or ramie, or of which these substances or any of them is the component material of chief value, weighing 4½ ounces or more per square yard:	
		Containing not more than 60 threads to the square inch, counting the warp and filling.	1¼ cents per square yard.
		Containing more than 60 and not more than 120 threads to the square inch.	2¼ cents per square yard.
		Containing more than 120 and not more than 180 threads to the square inch.	6 cents per square yard.
		Containing more than 180 threads to the square inch.....	9 cents per square yard.
		And in addition thereto, on all the foregoing.....	30 per cent ad valorem.
		Provided, That none of the foregoing * * * fabrics in this paragraph shall pay a less rate of duty than.....	50 per cent ad valorem
	357	Plain woven fabrics * * * of flax, hemp, or ramie, or of which these substances or any of them is the component material of chief value, including such as is known as shirting cloth, weighing less than 4½ ounces per square yard:	35 per cent ad valorem.
		Containing more than 100 threads to the square inch, counting the warp and filling.	35 per cent ad valorem.
		Containing not more than 100 threads to the square inch	30 per cent ad valorem.
	358	* * * all manufactures of flax, hemp, ramie, or other vegetable fiber, or of which these substances, or any of them, is the component material of chief value, not specially provided for in this section.	45 per cent ad valorem.
1913	280	All pile fabrics, whether or not the pile covers the entire surface, composed of flax, hemp, or ramie, or of which flax, hemp, or ramie is the component material of chief value, and all articles and manufactures made from such fabrics, not specially provided for in this section.	40 per cent ad valorem.
	283	Plain woven fabrics * * * of flax, hemp, or ramie, or of which these substances or any of them is the component material of chief value, including such as is known as shirting cloth.	30 per cent ad valorem.
	284	* * * all manufactures of flax, hemp, ramie, or other vegetable fiber, or of which these substances, or any of them, is the component material of chief value, not specially provided for in this section.	35 per cent ad valorem.
1922	1009	Woven fabrics * * * of flax, hemp, or ramie, or of which these substances or any of them is the component material of chief value (except such as are commonly used as paddings or interlinings in clothing):	
		Exceeding 30 and not exceeding 100 threads to the square inch, counting the warp and filling.	55 per cent ad valorem.
		Weighing not less than 4½ and not more than 12 ounces per square yard.	
		Exceeding 12 inches but not exceeding 24 inches in width....	
		Woven fabrics, such as are commonly used for paddings or interlinings in clothing, composed wholly or in chief value of flax, or hemp, or of which these substances or either of them is the component material of chief value:	
		Exceeding 30 and not exceeding 110 threads to the square inch, counting the warp and filling.	Do.
		Weighing not less than 4½ and not more than 12 ounces per square yard.	

Rates of duties on fabrics of flax, hemp, or ramie, 1883–1922—Continued.

Act of—	Paragraph.	Tariff classification or description.	Rate of duty.
1922	1010	Woven fabrics * * * of flax, hemp, ramie, or other vegetable fiber, except cotton, or of which these substances or any of them is the component material of chief value, not specially provided for.	40 per cent ad valorem.
	1011	Plain woven fabrics * * * of flax, hemp, ramie, or other vegetable fiber except cotton, weighing less than 4½ ounces per square yard.	35 per cent ad valorem.
	1012	Pile fabrics, composed wholly or in chief value of vegetable fiber other than cotton, cut or uncut, whether or not the pile covers the whole surface, and manufactures in any form, made or cut from any of the foregoing.	45 per cent ad valorem.
	1013	Table damask composed wholly or in chief value of vegetable fiber other than cotton, and manufactures composed wholly or in chief value of such damask.	40 per cent ad valorem.

Woven fabrics of flax, hemp, or ramie—Comparison of rates of duty under tariff acts of 1897, 1909, 1913, and 1922.[1]

[1] Tailors' paddings and table damask excluded from the act of 1922. Pile fabrics excluded in all acts. Table damask dutiable in act of 1922 at 40 per cent and on physical standards in other acts. Tailors' paddings from 31 to 110 threads to the square inch weighing from 4½ to 12 ounces per square yard are dutiable at 55 per cent and paddings of other weights and thread counts are dutiable at 40 per cent in act of 1922. In other acts paddings were dutiable on the basis of physical standards prescribed.

[2] 30 per cent if plain woven; 35 per cent if other than plain woven.

[3] 12 inches wide or less are "small wares," and are not included in this report.

[4] 35 per cent if plain woven; 40 per cent if other than plain woven.

[5] Based on imports during the period July 1, 1909, to October 3, 1913.

[6] Based on imports during the period July 1, 1897, to June 30, 1909.

PREFACE.

This is one of a series of Tariff Information Surveys prepared by the United States Tariff Commission and transmitted to the Committee on Ways and Means. The series covers all of the articles and commodities provided for in the tariff act of October 3, 1913, and others not specifically provided for. It is arranged in the numerical order for paragraphs of that act.

In some cases two or more paragraphs have been combined in one pamphlet. In doing this, industrial relationship of the articles has been followed when possible. In those instances where a paragraph has been treated under a preceding paragraph of the tariff act, reference is made to this fact at the point where the paragraph appears in numerical order. Where one grade of an article is dutiable and another grade of the same article is on the free list, the article is discussed under the dutiable paragraph, which appears first in numerical order in the tariff act. In certain instances articles of close industrial relationship and which occur in separate paragraphs of the tariff act have been combined under one paragraph for convenience of discussion. Reference is made to this fact at the point where the commodities would naturally occur in numerical order.

The first pamphlet in the series is an "Introduction and index," which contains:

1. An introductory chapter discussing the scope of the series and the general method of treatment.
2. An alphabetical index of the articles provided for in the tariff act of 1913, showing the paragraph of the act in which the article is provided for and, if discussed under a different paragraph, the number of such paragraph.
3. A list of the pamphlets in the series, showing the paragraphs and articles included in each pamphlet.

Thus, by use of this "Introduction and index," the exact location of the discussion relating to a given article or commodity can be ascertained.

In the preparation of this report the Tariff Commission had the services of John J. Cameron of its staff, and of others.

CONTENTS.

JUTE CLOTHS.

	Page.
Summary	9
I. Bagging for covering raw cotton	10
II. Nonprocessed burlap	12
III. Processed burlap	13

PART I. BAGGING FOR COVERING RAW COTTON.

Description and uses	14
Domestic production:	
Materials	15
Organization	17
Methods of production	18
Production	18
Consumption	19
Exports	21
Foreign production:	
United Kingdom	21
British India	22
Imports	22
Imports by countries	23
Competitive conditions	24
Tariff history	25
Tables:	
Imports by countries, 1895–1921	27
Imports for consumption, revenue, under tariff acts, 1890, 1894, 1897, 1909, and 1913	27
Prices of new domestic bagging, 1898–1921	28
Prices of imported bagging, 1914–1921	29
Prices of domestic rewoven bagging and sugar bag cloth, 1914–1921	29
Prices of domestic patches for covering cotton, 1916–1920	30
Rates of duty—cotton bagging, 1883–1913	30
Court and Treasury decisions	30

PART II. NONPROCESSED BURLAP.

Description and uses	33
Jute padding, buckram, and webbing	34
Substitutes	36
Domestic production	37
Equipment	37
Methods of production	37
Geographical location	37
Production	38
Foreign production:	
British India—	
India, the world's leading manufacturer of jute goods	39
Importance of the jute trade to India	40
Growth of the Indian jute industry	40
Number of sacking and hessian looms	44
Exports of raw jute and yarn	44
Exports of gunny cloth	45
Percentage of cloth shipments consisting of burlap	46
Exports of cloth to the United States, 1900–1921	46
Exports to other countries	47
Prices of cloth sent to each country	47
Trend of the Indian industry	48

Foreign production—Continued.
Dundee— Page.
The rise and decline of the Dundee jute industry 50
Exports to leading countries 52
Formation of the Jute Industries, Ltd 52
Imports:
Imports for consumption 52
Dominant position held by the British Empire 53
Types of cloth imported from Dundee and from Calcutta 54
Sizes and weights of cloth imported 54
Competitive conditions:
British India—
Causes for India's dominant position 55
Labor costs 56
United Kingdom 57
Tariff considerations:
Opinions of trade regarding duty on burlap 58
Duty necessary to promote domestic industry 58
Burlap as a source of revenue 59
Tariff history:
Tariff classification 60
Tables:
Domestic consumption of jute and burlap and production of jute bags, 1917 and 1918 62
Consumption of jute and burlap and production of bags for 50 leading domestic establishments, 1917 and 1918 63
Stocks of burlap in the United States on June 1, 1918, with six leading States, ranked in order of consumption 63
Imports by countries, 1905–1921 64
Imports for consumption, revenue 1895–1921 64
Revenue, by classes, derived from burlap, 1898–1914 65
Prices, 40-inch 10½-ounce burlap, at Calcutta, in January and July, 1890–1922 66
Prices of leading jute cloths at Dundee, 1899–1922 66
Prices, 40-inch 8-ounce and 40-inch 10½-ounce burlap at New York, 1918–1921 67

JUTE CLOTHS.

SUMMARY.

Jute is the world's cheapest fiber and, in quantity grown, is second only to cotton. The average yearly output of raw jute is about 8,000,000 bales of 400 pounds each. The low price of jute has caused jute fabrics to become the world's leading wrapping and sacking material. The causes for the low price of jute are: (1) Heavy production per acre; (2) cheap and abundant labor in British East India, to which country production is confined; (3) the ease with which the fiber can be prepared for spinning.

There are four leading cloths manufactured from the jute fiber, the combined domestic consumption of which amounted in 1920 to about 1,100,000,000 yards, principally burlap and cotton bagging. In ascending order of quality and value they commonly rank as follows: (1) Bagging, divided into two classes, (*a*) cotton bagging with single warp usually consisting of about four threads to the square inch, used for covering raw cotton; and (*b*) double-warp (D. W.) bagging, with about 16 threads to the square inch and extensively employed for wrapping; (2) twilled sacking, with about 18 threads to the square inch, enters the United States chiefly as containers for foreign products, principally raw sugar; (3) tarpaulin, with about 30 threads to the square inch, used as covering and as the foundation of waterproofed and brattice cloths, and (4) burlap or hessian, with about 24 threads to the square inch, employed most extensively as bag material, for baling purposes, and as a backing for linoleum.

These cloths are further differentiated by weave, weight, and raw material used in their manufacture. Burlap and cotton bagging are woven with one thread over and one under in both warp and weft. Tarpaulin and double-warp bagging are distinguished by their double-warp construction; two warp threads woven side by side as one. Sacking is usually woven with a plain twill, made by passing each warp thread over two and under one weft thread so as to produce a diagonal effect.

While all four cloths are woven from single jute yarns, sacking, because it is woven with a twill, is excluded from paragraphs 279 and 408 of the act of 1913 by the words "plain woven." Sacking, though a quality of cloth lower than burlap, has not been specially provided for and has been subject to higher duties under the general provisions for manufactures of vegetable fibers. The difference in duties has tended to make imports small.

Plain woven jute fabrics are divided by the act of 1913 into three classes: (1) Bagging for raw cotton, which is defined as "Bagging for cotton * * * not exceeding 16 threads to the square inch, counting the warp and filling, and weighing not less than 15 ounces

per square yard; (2) burlap, burlaplin, double-warp bagging, referred to as plain woven fabrics of single jute yarns, by whatever name known; (3) fabrics of single jute yarns, by whatever name known, bleached, dyed, colored, etc. A distinction between the first two classes of fabrics is urged in view of the market difference in the quality of the cloth and the tariff problems connected with each. Burlap, the finest jute fabric, is practically all imported; cotton bagging, the coarsest, is manufactured mainly in domestic mills. Burlap constitutes the bulk of the cloths falling under the second and third classes.

PROVISIONS IN TARIFF ACT OF 1913.

Par. 408: "Bagging for cotton, gunny cloth, and similar fabrics, suitable for covering cotton, composed of single yarns made of jute, jute butts, jerg, Russian jerg, New Zealand jerg, Norwegian jerg, linen, mill waste, cotton tares, or other material not bleached, dyed, colored, stained, painted, or printed, not exceeding sixteen threads to the square inch, counting the warp and filling, and weighing not less than fifteen ounces per square yard. * * * Free."

Par. 408. "* * * Plain woven fabrics of single jute yarns, by whatever name known, not bleached, dyed, colored, stained, painted, or rendered noninflammable by any process. * * * Free."

Par. 270: Plain woven fabrics of single jute yarns, by whatever name known, bleached, dyed, colored, stained, painted, printed, or rendered noninflammable by any process, 35 per centum ad valorem."

This survey follows the arrangement of the tariff act of 1913. It summarizes the industry and then describes in detail the domestic trade in jute cloths under three headings: Bagging for Covering Raw Cotton; Nonprocessed Burlap; and Processed Burlap.

I. Bagging for Covering Raw Cotton.

Cotton bagging is the coarse loosely woven jute fabric used for covering raw cotton. The leading size is 45 inches wide and weighs 2 pounds. The best domestic grades are made from yarn spun from jute butts—the ends of jute fiber laid aside as being too coarse for the manufacture of burlap. The bulk of the bagging produced in the United States consists of grades manufactured from jute butts mixed with various proportions of old bagging, cordage, and mill wastes.

The American cotton crop in 1920, including linters, was 13,563,208 bales. Allowing 7 yards of bagging to the bale, as ready for shipment, about 97,000,000 yards of covering were required in 1920. The American production of new bagging in the same time amounted to about 52,686,000 yards of 45-inch width. From the sales and estimates made by the leading firms selling each type of bagging, there were used in covering the 1920 crop approximately 46,869,000 linear yards of new bagging; 5,446,000 yards of imported bagging;[1] 7,396,000 yards of rewoven bagging, and 9,706,000 yards of sugar-bag

[1] Imports of bagging in the calendar year 1920 amounted to 7,261,904 square yards, or about 5,446,000 running yards, and in 1921, to 3,372,000 square yards, or about 2,529,000 running yards.

cloth. The remaining 27,625,000 yards, or 28 per cent, consisted of material which had been used before. The amount of secondhand bagging consumed in 1920 was much larger than usual.

Imports in the fiscal years 1892–1920,[2] ranging between a minimum of 618,708 square yards in 1894 and a maximum of 19,817,860 in 1907, averaged 7,728,912 square yards, or 5,796,000 running yards. In the years 1892–1919 the American cotton crop, including linters, averaged 11,597,233 bales. During the last quarter of a century about three-fourths of the total value of foreign bagging consumed in the the United States was furnished by the United Kingdom and all but 2 or 3 per cent of the remainder by British India. In the fiscal years 1914–1919 [3] shipments from the United Kingdom and from British India constituted 77 and 18 per cent, respectively, of the total quantity imported in these years. During 1920 and 1921, however, India furnished 67 and 56 per cent, respectively, as against 32 and 37 per cent by the United Kingdom in the same years.

The bulk of the bagging received from the United Kingdom consists of secondhand bagging and old bagging for remanufacture. The Indian product is superior to the best domestic brands, since it is more closely woven and made entirely from jute butts.

The volume of imports has been small because of the position of the two domestic companies, which are the world's largest manufacturers of bagging, and because of the risks involved in supplying a demand which fluctuates from season to season. These two companies have been long prominent in this field. Each has a large organization, and by making a number of products closely related to bagging they save in overhead expenses.

The first of these companies and a subsidiary of the second, the latter incorporated with a capital stock of $5,000,000, are now each building a mill in India. Each mill has already received shipments of the bagging machinery formerly operated in the United States. One of the mills will run solely on bagging, whereas the second will produce both bagging and burlap.

1921 (calendar year)		3,372,000	309,897	Free.	9.2	Free.

[2] 1892 is the first full year for which data regarding the quantity of imports for consumption are available.
[3] The quantities of bagging imported by countries are first given beginning with 1912.
[a] Census, "Bags and bagging," principally bagging.
[b] From July 1, 1913, to Oct. 3, 1913.
[c] From Oct. 4, 1913, to June 30, 1914.
[d] Census, Bagging, new and rewoven, valued at $11,340,000.

II. NONPROCESSED BURLAP.

Burlap is a plain woven cloth made from the best qualities of raw jute, ranging from 27 to 150 inches in width and from 6 to 16 ounces to the linear yard. The standard is the 40 inch, 10½ ounce. Burlap is the world's leading sacking and wrapping material. Four-fifths of that consumed in the United States is made into bags, used as containers for grain, feed, bran, flour, granulated sugar, and for a number of bulky commodities. It is also used for wrapping a great variety of products ranging from cotton cloths to dynamos; for tailor's padding; as the constituent basis of brattice cloth, fireproofed for use as screens in mines; and as upholstery materials and horse clothing. About 33,000,000 square yards were used in 1919 as backings for linoleum and floor cloths.

The domestic production of jute cloths, other than cotton bagging, has always been negligible. The record output in recent years was 7,292,000 linear yards of burlap in 1918—about 1 per cent of the domestic consumption. In 1919 and 1920 production was 5,659,580 and 4,879,642 linear yards, respectively. The above totals do not include fabrics of all jute, or of jute and cotton, used as paddings or interlinings in coats. As in the case of burlap, the production of paddings reached its height in 1918 with 8,540,000 linear yards, and then declined to 4,200,000 yards in 1919 and 4,150,000 yards in 1920. Exclusive of the amount produced by two prisons, eight companies, since 1914, have woven these fabrics, seven participating because of war conditions. Five of these have since discontinued weaving these fabrics.

TABLE 2.—*Domestic production and imports of nonprocessed burlap.*[a]

1914[b]		92,645,152	8,044,180	1,734,722	8.7	21.56
1914[c]		431,039,133	36,437,228	Free.	8.5	Free.
1915		308,443,353	27,955,560	Free.	7.0	Free.
1916		382,344,357	34,231,997	Free.	8.9	Free.
1917		446,980,546	48,323,839	Free.	10.8	Free.
1918	[d]15,832,000	442,193,870	58,746,318	Free.	13.3	Free.
1919	9,859,580	410,129,359	72,396,222	Free.	17.6	Free.
1920	9,029,642	541,143,114	88,027,296	Free.	16.3	Free.
1921		536,904,927	64,077,225	Free.	11.9	Free.
1921 (calendar year)		474,039,104	41,264,713	Free.	8.7	Free.

[a] Includes all burlaps, specified and nonspecified, from July 1, 1909, to Oct. 3, 1913.
[b] From July 1, 1913, to Oct. 3, 1913, inclusive.
[c] Burlaps, not bleached, dyed, etc.
[d] Burlap, and paddings of jute, or in chief value of jute. To convert these to pounds, a linear yard may be taken as weighing 9 ounces.

The United States is the world's largest consumer of burlap. Imports constitute two-thirds of the jute cloth exported from British India, and one-half of those from Dundee, Scotland, The quantity and value of burlap imported during 1905–1921 [4] from these sources, are shown in the following table:

[4] The quantity of burlap received from different countries is first available for 1905.

TABLE 3.—*Imports of burlap from British India and the United Kingdom compared with total imports.*

Fiscal year.	Total imports, all sources.		From British India.	From United Kingdom.
	Quantity.	Value.	Quantity.	Quantity.
	Pounds.		*Pounds.*	*Pounds.*
1905–1909	317,136,742	$21,379,161	257,022,688	58,672,691
1910–1914	421,383,181	29,420,977	358,704,219	59,867,928
1915–1919	415,483,840	48,331,193	373,514,527	38,020,795
1920	541,113,614	88,020,057	482,932,925	53,402,830
1921	537,034,044	64,086,584	497,668,374	33,753,936
1921 (calendar year)	474,168,221	41,279,072	444,669,569	26,064,594

Calcutta, India, and Dundee, Scotland, are the world's leading jute centers. Burlap imported from Calcutta is used for bag material, and for wrapping and baling purposes, whereas that from Dundee consists of cloth, which requires special machinery or a high grade of workmanship, such as tailors' paddings and backings for linoleum.

Although under the acts of 1897 and 1909 nonprocessed burlap was subject to a duty, averaging 1.65 cents per pound (about 1 cent per linear yard), or 26.75 per cent ad valorem, American manufacturers considered it unprofitable to attempt manufacture in competition with India.

III. PROCESSED BURLAP.

The leading processed cloths falling under paragraph 279 are: (1) Burlap, tarpaulin, and double-warp bagging which have been rendered noninflammable, as brattice cloth; (2) and burlap which has been dyed or printed for upholstery or decorative purposes.

Reports from individual establishments show a marked advance since 1914 in the domestic production of brattice cloth converted from jute fabrics. The cloth converted in 1920 amounted to 3,380,826 square yards, with an estimated value of $899,000.

Imports for consumption under this classification, first enacted in 1913, ranged in the years 1914–1921 from 3,768,108 pounds in 1914 [5] to 1,140,362 pounds in 1918, with a yearly average of 2,092,244 pounds, valued at $258,637. Imports consist for the most part of brattice cloth. Two-thirds of the imports come from the United Kingdom, and British India furnishes the bulk of the remainder.

TABLE 4.—*Imports of processed burlap.*[a]

Fiscal year.	Imports for consumption.		Duty.	Value per unit of quantity.	Equivalent ad valorem rate.
	Quantity.	Value.			
	Pounds.			*Cts. per lb.*	*Per cent.*
1914 [b]	3,768,108	$345,697	$34,569	9.2	10
1915	2,018,540	164,092	16,409	8.1	10
1916	1,840,311	182,025	18,202	9.9	10

1919	2,193,896	344,803	34,480	15.7	10
1920	1,818,541	345,856	34,585	19.0	10
1921	1,571,657	235,977	23,597	15.0	10
1921 (calendar year)	1,016,418	105,263	.....	10.3	10

[a] Classification first adopted in 1913. [b] From Oct. 4, 1913, to June 30, 1914.

NOTE.—No figures are available regarding total production of cloth imported in the gray, and printed, dyed, etc., in this country. The amount so processed in the United States is many times larger than imports of burlap which has been dyed, etc.

[5] From Oct. 4, 1913, to June 30, 1914.

PART I.

BAGGING FOR COVERING RAW COTTON.

DESCRIPTION AND USES.

Cotton bagging is the coarse jute cloth employed for covering raw cotton. The type used for baling the American cotton crop is the coarsest bagging made and the lowest grade of jute fabric woven. The better grades of bagging are usually plain woven with a double warp thread. The greater part of the bagging consumed in this country, however, has a single warp. The consumption of double warp bagging will be discussed in connection with the trade in burlap.

The importance of the domestic trade in cotton bagging may be judged from the fact that in the season of 1920 the American cotton crop, including linters, totaled 13,863,208 bales, each bale requiring an average of 7 yards of covering.

Cotton bagging is usually woven from yarns produced from the lowest grades of jute butts or cuttings, the woody ends of the stalks cut off when preparing the fiber for shipment.

The bulk of the cotton bagging woven in the United States has about two warp threads and two weft threads per square inch, and weighs about two pounds to the linear yard. In the tariff acts of 1897, 1909, and 1913 imports of cotton bagging under a specific paragraph have been restricted to such covering having not more than 16 threads to the square inch, counting the warp and filling, and weighing not less than 15 ounces to the square yard. The acts of 1897 and 1909 made specific mention of two classes of burlap: (1) not exceeding 30 threads to the square inch, counting the warp and filling, weighing 6 ounces or over per square yard; and (2) not exceeding 55 threads per square inch, counting warp and filling.

There are three grades of bagging woven in the United States. The first is manufactured from jute butts with a small part of waste; the second, from jute butts mixed with 60 or more per cent of other materials, principaly old bagging, and cordage wastes; and the third of practically all old bagging with the addition of a small amount of hard fiber.

These grades are made in various widths and weights. The usual width is 45 inches. There is greater diversity, however, in the matter of weights, which run 2, 2¼, 2½, and 3 pounds to the yard, with 2 pounds to the linear yard as the dominant weight. Various trade names such as "American," "York," "Peerless," "Hub," and "Calcutta" are used to designate the quality and weight of the different classes of bagging.

Six yards of material are used in covering the average bale as it comes from the gin. The bagging is held in place by six ties weighing about 1½ pounds each, making the actual tare amount to about 12 pounds. American mills limit the tare to 24 pounds per compressed bale, whereas European purchasers usually buy on the basis of 4 per cent gross weight.

The production of "compress labels"—patches of greater weight than ordinary bagging, added at the time of compression to equal the purchaser's allowance for tare—forms an important part of the domestic trade in cotton bagging.

About 80 per cent of the American cotton crop is sent north and abroad. Previous to shipment all cotton that is exported, and a very large part of that consumed in the United States, is compressed, which reduces the size of the bale one-half. In order to make up the difference between the actual and estimated tare, it is a common practice for shippers, when rebaling at a compress, to add to each side of the bale a compress label. When the shipment is intended for Europe, the labels weight about 4 pounds each, bringing the total weight of the bagging up to 20 pounds.

The leading weights and sizes of compress labels are:

pounds	30 by 36 inches
½ pounds	30 by 42 inches
6 pounds	36 by 44 inches
pounds	30 by 48 inches
½ pounds	30 by 54 inches

Large amounts of cloth made from secondhand twilled sugar bags are utilized for covering cotton. These bags, which are not manufactured in the United States, measure 29 inches by 48 inches and weigh twice as much per square yard as burlap bags of domestic origin. They enter this country as containers of raw sugar shipped in 320-pound quantities. The leading domestic use of such bags is for sacking vegetables, cottonseed cake, and other bulky commodities. The quantity consumed in a given year for covering cotton depends upon the price offered for their use as sacks. As a rule, only the poorer grades are used for covering purposes.

The use of secondhand bagging is extensive. A number of southern mills sell their secondhand ties and bagging directly to farmers and ginners. After bagging has been used a number of times it becomes so worn that it must be rewoven or mixed with jute butts or cordage wastes to be serviceable any longer for covering purposes. The reweaving is done by first running the material through a special type of picker, which tears it up into its original fibers; next it is recarded, respun, and rewoven.

Domestic Production.

MATERIALS.

Jute is the fiber generally used in the manufacture of cotton bagging. The amount normally consumed of other fibers such as Russian seg, New Zealand tow, Norwegian tow, or of fiber wastes such as cotton tares and mill wastes, is small.

With the exception of cotton, more pounds of jute are produced than of any other fiber. Unlike cotton, however, the production of jute is confined almost exclusively to British India, which levies a duty on all exports of jute and its manufactures.[1] The rate in 1921, on the basis of the rupee being equal to 32.44 cents, amounted to $0.40

[1] No preferential duty on jute is given to countries of the British Empire, though Dundee has been urging it. The views of the English jute trade on this subject are set forth on page 39 of the Report of the Committee to Consider the Position of the Textile Trades after the War—London, 1918.

per bale of 400 pounds of jute butts, and to $1.46 for the same quantity of long jute. On hessian the duty was $9.73 per ton of 2,240 pounds as against $6.49 for the same quantity of sacking.[2]

Jute is ordinarily the world's cheapest fiber. The causes for its low price are: (1) The heavy production per acre; (2) the fact that the production of jute is confined to a part of the world where labor is cheap and abundant; (3) the ease with which the fiber can be prepared for spinning. Although jute is the cheapest fiber, yet it is too expensive to use any but the ends (butts) in the production of cotton bagging.

When being prepared for shipment, the jute fiber is divided into three classes:

1. Jute butts—consumed chiefly in the manufacture of sacking weft, bagging, and paper.

2. Jute rejections—material either damaged or barky or knotty, and therefore unsuitable for manufacture into burlap.

3. Long jute—fiber utilized in spinning the yarns used as the warp and weft in hessian, and as the warp in sacking.

The United States is the world's largest importer of jute butts, which have been free in all acts since 1891. The domestic consumption totaled 29,832 tons in 1920. By 10-year periods, the American consumption has averaged yearly:

	Tons.
1891-1900	64,089
1901-1910	43,790
1911-1920	30,583

A number of different grades of jute butts are imported. "Mixings," the cheapest and the grade used in the manufacture of bagging, represents the bulk of the butts imported. The price of "mixings" per pound landed in New York was 2.5 to 3 cents in January, 1913; 2.75 cents in December, 1913; 1.4 to 1.5 cents in March, 1921; and 2 cents in July, 1921. The greater part of imports is consigned to the two American companies that turn out all but a small part of the bagging produced in the United States.

The lack of tonnage during the closing years of the war created a scarcity of jute butts, which led one of the largest producers of bagging in the United States to develop the desert fiber, yucca, which grows in West Texas and New Mexico. Before the close of the war this company had erected a plant and was extensively using yucca in the manufacture of bagging. At the close of the war, this bagging concern was planning to produce about 40,000 tons of yucca fiber per year. Increases in domestic railroad rates, while the ocean rates from India were being lowered, combined with advances in domestic wages, coal, and other supplies, made the cost of yucca prohibitive as compared with jute butts imported from India.[3] As the result of these conditions, the company was obliged to discontinue the production of yucca.

A number of waste materials, other than those specifically mentioned in the clause relating to cotton bagging, which might be utilized in its manufacture, are free of duty. The last clause of paragraph 408 provides that the waste of bagging, burlap, and similar fabrics suitable for the manufacture of paper shall be ad-

[2] Indian tariff act No. VI of 1917, effective Mar. 1, 1917.
[3] Freight charges from India to ports in the United States are discussed on p. 52.

mitted free of duty. Likewise, paragraph 566 grants free entry for "paper stock * * * rope ends, waste rope, and waste bagging, * * * including old gunny cloth and old gunny bags, used chiefly for paper making."

Secondhand jute bags, twilled or colored, which have become so worn, torn, or cut as to be unsuitable for use as bags, and not classable as rags or paper stock, are dutiable at 10 per cent under paragraph 384 of the act of 1913, as waste not specifically provided for.[4]

ORGANIZATION.

All but 2 or 3 per cent of the new bagging produced in the United States is the output of two companies, which are the world's leading manufacturers of this article. The first of these companies manufactures about twice the quantity produced by the second. Sales by the first company amounted in 1915 to about $9,500,000; in 1916 to $16,000,000; in 1917 to $21,000,000; in 1918 to $24,000,000; in 1919 to $21,000,000; and in 1920 to $23,000,000. This firm started operating in 1911, succeeding a company of the same name, which had begun business in 1890. The second company's gross sales in 1920 amounted to $19,210,000 as compared with $16,146,000 for 1919 and $14,183,000 for 1918. It commenced operating in 1914 as the successor to a company of the same name, incorporated in 1868.

Both companies make fiber products the chief end of their output. The leading products of the first are manila, sisal cordage, and jute and hemp twines; and of the second, jute and hemp twines, and jute carpet yarns.

The first company has five plants located in as many States, namely, St. Louis, Mo.; Charleston, S. C.; Brooklyn, N. Y.; Philadelphia, Pa.; and East St. Louis, Ill. Only the first three mills produce bagging. In recent years, an increasing percentage of this company's total output has come from the mills located at Charleston and St. Louis. In 1920 about three-quarters of its total production was woven in these two mills. The second company has its 11 mills all located at Ludlow, Mass. Only one of these works on cotton bagging.

Likewise, two companies—one located in the South and the other in the North—dominate the trade in sugar bag cloth. Both companies have been engaged in this line for more than 40 years. The southern firm, which specializes in the manufacture of 100-pound granulated sugar bags, concentrates its efforts in the bagging trade to making patches or compress labels from jute butts, from sugar-bag cloth, and from other materials. This company early in 1921 had a capitalization of $2,500,000 and was giving employment to about 150 persons. The firm located in the North, which makes the sale of secondhand raw sugar bags for sacking purposes the leading end of its business, employed in 1920 about 300 people in two plants valued at over $1,000,000.

The trade in rewoven bagging is largely divided among four firms. One of the largest firms specializing in this line was operating in 1921 two plants with a value in excess of $500,000.

[4] McGettrick v. United States, 11 Ct. Cust. Appls. —; T. D. 38727 of 1921.

The operatives employed in these plants consist largely of women. In the carding, spinning, and winding operations they greatly outnumber the men. Two companies have women as weavers or rovers, whereas a third employs only men.

METHODS OF PRODUCTION.

The production of cotton bagging calls for a minimum of textile machinery. The machinery required, in the order of its use, is as follows: Bale breaker; softener; breaker card; finisher card; rotary gill-spinning frame; cop-winding machine; loom; roll-winding machine. For making second-grade bagging, there are also required waste-cleaning machines and dreadnought pickers.

One of the two leading domestic concerns manufacturing bagging makes all its bagging machinery, whereas the second imports a part of that used in the processes prior to weaving. The act of 1913 lowered the duty on jute machinery from 45 to 20 per cent.

PRODUCTION.

The annual cotton yield in the years 1909–1912, and the bagging output of two companies, which were then weaving all the new bagging produced in the United States, are shown in the following table compiled from a report published by the Department of Commerce in 1913:[5]

TABLE 5.—*Production of raw cotton and cotton bagging, 1909–1912.*

Year.	Cotton crop, including linters.	Bagging for covering cotton.		
		Production by American manufacturing company.[1]	Production by Ludlow manufacturing associates.	Total production.
	500-lb. bales.	*Linear yards.*	*Linear yards.*	*Linear yards.*
1909	10,315,382	50,638,665	16,861,155	67,499,820
1910	12,005,688	36,314,359	21,270,475	57,584,834
1911	16,250,276	[2] 47,875,735	18,310,760	66,186,495
1912	14,313,015	[2] 31,856,450	20,879,180	52,735,630

[1] Contains small amounts of bagging which were purchased.
[2] Includes production of compressed labels and cut pieces, which have been reduced to running yards on the basis of 3.6 pounds to the yard.

In the years 1914–1920 the average yearly production of bagging was below the prewar output. The production of the largest company in these years ranged between 52,052,455 and 28,258,728 running yards; of the second, between 22,000,000 and 16,000,000 running yards, and of a third company, which began manufacturing new patches in 1916, between 4,368,000 pounds and 3,183,000 pounds.

The decline was confined to the last part of the period. Following the record cotton crops of 14,795,367 bales in 1913 and 16,991,830 bales in 1914, the output of bagging expanded in anticipation of continued large yields. The subsequent decline in the years 1916–1918 was due to: (1) A falling off in the cotton crop from the high levels reached in 1911–1914; (2) the difficulty during the war in securing raw materials; (3) the increased consumption during 1917–1920 of secondhand bagging, sugar-bag cloth, and rewoven bagging.

[5] "Cotton Bagging and Ties."—Department of Commerce, 1913, pp. 20 and 27.

At the close of the war production tended to become normal in its relation to the cotton crop. The amount of new bagging, including new patches, woven in 1919 is estimated at 56,510,000 linear yards of 45 inches, or about 4.7 yards of new material for each of the 12,020,000 bales grown,[6] the same ratio as in 1910, when the cotton crop was 12,005,000 bales and 57,584,000 yards of bagging were produced. Production in 1920 did not expand with the increased crop of that season. New bagging and patches woven in 1920 amounted to about 52,686,000 yards. The cotton crop of 1920 amounted, in equivalent 500-pound bales, to 13,439,603 bales of lint cotton and 423,605 bales of linters, a total of 13,863,208 bales. Assuming that 7 yards of bagging to the bale, 97,042,456 yards of material were required for covering the 1920 crop.

Manufacturers report that the bulk of their output consists of lower grades in response to the demand, which places more emphasis on the bagging being cheap and heavy than on its being durable. The increasing proportion of bagging made from rewoven fibers and mill wastes is shown by the marked decline during the years 1891–1920 in imports of jute butts.

CONSUMPTION.

Table 6 furnishes a basis for estimating the amount of bagging consumed during the period 1900–1920. Six yards of material are customarily used for wrapping the bale as it comes from the gin. About four-fifths of the cotton grown in the South is shipped North and to Europe. An allowance of an additional yard may be made for covering sample holes and for compress labels, making an average of 7 yards used in wrapping the ordinary cotton bale.

TABLE 6.—*Production of raw cotton, including linters, 1900–1920.*[1]

Year.	Bales (500-pound).	Year.	Bales (500-pound).
1900	10,266,527	1915	12,122,961
1905	10,804,556	1916	12,780,644
1910	12,005,688	1917	12,428,094
1911	16,250,276	1918	12,970,048
1912	14,313,015	1919	12,028,732
1913	14,795,367	1920	13,863,208
1914	16,991,830		

[1] Figures for 1900–1919 are from "Cotton Production and Distribution, 1919–1920": Department of Commerce, Bulletin No. 145, p. 13. Statistics relating to the cotton crop of 1920, exclusive of linters, are given in "Cotton production in the United States, Crop of 1920," published by the Bureau of the Census, June 16, 1921.

In recent years a smaller amount of new bagging has been used in covering the average cotton bale. In the period 1909–1912 the proportion was about 5.43 yards of new material to 1.57 yards of second-hand bagging, rewoven bagging, and sugar-bag cloth.[7] Since 1914

[6] Census figures give the domestic production of bagging in 1919 as 75,205,000 square yards, valued at $11,340,000. These totals relate only to amounts of bagging woven and do not differentiate between material made from new fibers and that from rewoven fibers.

[7] "Cotton Bagging and Ties," pp. 36, 37.

there has been a marked increase in the consumption of secondhand bagging and substitutes. Reports from two prominent dealers in sugar-bag cloth show a decided advance in their sales during 1917–1920 of such covering and patches as compared with the first years of the war. The quantities sold by each in 1920 were below the totals of the preceding two years, because fewer bags than usual were available for covering purposes. The greater demand and the higher prices obtainable for bags of every description made it more profitable to patch these for sacking commodities than to cut them up for use as bagging. The amounts of bagging rewoven by one of the largest companies specializing in that line was from 25 to 37½ per cent greater in the years 1918–1920 than in 1914.

To ascertain the proportion of total cloth used in 1919 and 1920 for covering cotton consisting of (1) new bagging, (2) rewoven bagging, (3) sugar-bag cloth, and (4) secondhand bagging, the Commission obtained reports from the leading firms in each group, giving its production and sales of each type for each of these years. The season for selling bagging is practically limited to the period April-November, making sales within the calendar year coincide to a large extent with the amounts used in covering the crop of a given year. Sales of new bagging and patches, as based on the reports of these firms, and on the best estimates obtainable, were about 51,427,000 linear yards in 1919 and about 46,869,000 linear yards for 1920. The cotton crops, including linters, in these years amounted to 12,028,732 bales and 13,863,208 bales, respectively. Assuming that 7 yards of bagging were used in covering the average bale, 84,201,112 yards of material were required for the 1919 crop and 97,042,456 yards for the 1920 crop. Reckoning that all the bagging imported in the calendar years 1919 and 1920 was new and used on the crops of those years, a total of 58,026,616 linear yards of new material was consumed in 1919, and of 52,315,428 in 1920. As compared with an average of 5.43 yards of new bagging for each bale of cotton grown in the years 1909–1912, 4.8 yards were used in 1919 and 3.8 yards in 1920.

A table, based on sales in 1919 and 1920, showing the relative consumption of new bagging, imported bagging, and substitutes, when compared with a similar table published in 1913 by the Department of Commerce, indicates that the only marked change in 1919 from prewar years was an increase from 2 to 14 per cent in the consumption of sugar-bag cloth, cutting down the amounts of new and secondhand bagging used in that year. The figures for 1920, however, show a decided variance. Only in the case of rewoven bagging was the amount and percentage the same. Notwithstanding a larger cotton crop than the year previous, the quantity of new bagging, imported bagging, and sugar-bag cloth declined. Secondhand bagging in 1920 accounted for 28 per cent of all the material used.

TABLE 7.—*Estimated* [1] *consumption of various types of cotton bagging in 1909–1912, 1919, and 1920.*

	Amounts sold, in running yards.			Per cent of total sold in—		
	1909–1912	1919	1920	1909–1912	1919	1920
New bagging	254,398,354	51,427,000	46,869,000	69	61.07	48.29
Imported bagging	32,906,574	[2] 6,599,616	5,446,428	9	7.83	5.61
Rewoven bagging	24,000,000	8,065,000	7,396,000	7	9.57	7.62
Sugar-bag cloth	7,000,000	12,056,000	9,706,000	2	14.31	10.00
Secondhand bagging	50,000,000	6,053,496	27,625,028	13	7.22	28.48
Total consumption	368,304,928	84,201,112	97,042,456	100	100.00	100.00

[1] Based on actual sales and imports amounting in 1919 to 59,079,476 linear yards and in 1920 to 51,903,727 linear yards.

[2] Imports for the calendar years 1919 and 1920 amounted to 8,799,488 square yards and 7,261,904 square yards, respectively. These totals have been converted into linear yards of 45 inches in width, as have all figures in this column.

EXPORTS.

The type of cotton bagging woven in the United States for baling cotton is peculiarly American, since its use is limited to the domestic crop. American cotton is the poorest baled in the world. The demand places the emphasis on bagging that is cheap and heavy rather than on a fabric strong enough to withstand the action of hooks when being handled, or of mesh fine enough to protect the cotton from the action of the elements.

"That the cotton received from the United States at European ports usually is in much worse condition than that received from other countries, as stated by numerous consuls and special agents of the Department of Commerce and Labor, is verified by the photographs of actual shipments. One reason may be, as foreign importers complain, that since they are largely dependent on cotton from the United States, and the producers in the United States know this fact, the latter are indifferent in the manner in which it is packed. But this does not prevent the loss really coming back on the producer."[8]

FOREIGN PRODUCTION.

Statistics of foreign Governments do not show exports of cotton bagging apart from other jute cloths. As compared with shipments of burlap and sacking bags, those of cotton bagging are very small.

UNITED KINGDOM.

The leading English mills manufacturing cotton bagging are reported to be William Cleghorn (Ltd.), of Dundee, and Peter Marsh & Sons, of Liverpool. Production by these firms is occasional. Shipments of bagging from Dundee to the United States in the calendar years 1919 and 1920 amounted to 199,999 and 944,625 square yards, respectively.

[8] "Packing for Export." No. 4. Miscellaneous Series, Department of Commerce and Labor, 1909. This report contains a number of photographs showing shipments from various countries at arrival upon destination. A more recent discussion of this subject is to be found in a paper on "Needed Reforms in the Ginning, Baling, and Compressing of Cotton," read before the Second World Cotton Conference at Manchester, England, June 21, 1921.

A number of American bagging concerns import secondhand bagging from the United Kingdom for the purpose of making it into yarn. One of the firms in the South, reweaving bagging, reports that it consumes annually from fifteen to twenty million pounds of secondhand gunny bagging, a part of which is purchased from mills located in Manchester, England.

The United Kingdom consumes about one-fifth of all the cotton grown in the world, ranking second to the United States. About two-fifths of American exports are consigned to the United Kingdom. Shipments to the United States form an outlet for surplus secondhand bagging.

BRITISH INDIA.

The production of cotton bagging in India has never been large. With one exception all the Indian mills that have woven any cotton bagging in the past have produced it as incidental to their manufacture of burlap and sacking. Before the war there were five Indian mills that wove bagging. An American importer estimates their annual production as follows:

TABLE 8.—*Indian jute mills manufacturing cotton bagging.*

Name of mill.	Estimated annual production of cotton bagging shortly before 1914.	Name of mill.	Estimated annual production of cotton bagging shortly before 1914.
	Linear yards.		*Linear yards.*
Alliance	2,000,000	Lansdowne	2,000,000
Hastings	2,000,000	Narcoldanga	2,000,000
Kinnison	500,000		

The last, Narcoldanga, produces bagging exclusively. On January 1, 1921, this mill had 14 sacking looms.[9]

The representative of a domestic bagging company, who visited India in 1920, reports only two mills manufacturing bagging, namely, Lansdowne and Narcoldanga, the former an up-to-date and efficient concern preparing to double its plant.

The practice in Calcutta is to manufacture on order and not to carry stock, as in the United States.

India's production of gunny cloth for covering cotton is not limited to supplying the demand of the United States. As a grower of this commodity India ranks second, furnishing, in 1919, 22.4 per cent of the world's consumption.[10] Raw cotton is India's leading export. An examination of India's trade returns for the 30 years previous to 1920 shows that on 18 occasions India's chief exports were raw and manufactured cotton, principally raw.

IMPORTS.

Annual imports of cotton bagging for consumption during the period 1892[11]–1921 were greatest in the decade 1901–1910.

[9] Indian jute mills and their looms as of Jan. 1, 1921, pp. 41, 42.
[10] Cotton Production and Distribution, Season of 1919-20; Department of Commerce, Bulletin, 145, p. 79.
[11] 1892 is the first full year for which imports of cotton bagging, on the basis of square yards, are available.

TABLE 9.—*Imports of cotton bagging into the United States, 1892–1921.*

Period, fiscal year.	Average annual quantity.	Average annual value.	Period, fiscal year.	Average annual quantity.	Average annual value.
	Square yards.			*Square yards.*	
1892–1900	4,055,414	$152,715	1911–1920	7,196,310	$542,952
1901–1910	11,162,067	566,409	1921	4,873,711	511,766

In the decade 1901–1910 the domestic production of cotton, including linters, advanced about 27 per cent, or from an average of 9,102,000 bales during the years 1892–1900 to 11,591,000 for the following 10 years.

In the period 1892–1920 imports of bagging were smallest in 1894, with 618,708 square yards, valued at $32,709, and greatest in 1907, with 19,817,860 square yards, valued at $1,215,446.

Imports showed the greatest advance in quantity during the years 1903–1907, when they increased steadily year by year from 5,417,039 square yards to the peak reached in 1907. Accompanying this rapid advance was a decline in the equivalent ad valorem duty from 15.26 to 9.78 per cent. Under the act of 1913 bagging was exempt from duty.

The war seriously interfered with shipments of bagging. From a total of 9,648,484 square yards in the fiscal year 1915 they fell to 1,781,889 square yards in 1918.

Since 1918 imports have tended to remain at the level of war years. From 2,912,524 square yards in the fiscal year 1919 shipments advanced to 9,332,239 square yards in 1920, but fell to 4,873,711 square yards during the fiscal year ending June 30, 1921.

IMPORTS BY COUNTRIES.

Since the close of the war British East India has supplied the United States with the greater part of its foreign bagging—in the fiscal year 1919, 67.81 per cent; in 1920, 80.99 per cent; and in 1921, 56.71 per cent. Imports from the United Kingdom, which supplies all but a small part of the remainder, were 32.55, 17.55, and 37.49 per cent, respectively, for those years.

This is in striking contrast to the previous quarter of a century, when bagging of English manufacture constituted by far the greater part of the domestic consumption. From 1895 to 1918[12] in two years only—1898 and 1902—did the value of shipments from India exceed those from the United Kingdom. By five-year periods since 1895 imports from the United Kingdom have ranged between 60 and 80 per cent of the total value as against 39 and 19 per cent from British India.

Indian bagging is superior to that made by the English; it is made entirely from jute butts, is woven with more threads to the square inch, and is in every way stronger and more suitable for covering cotton. Calcutta bagging finds its greatest use in the Mississippi Delta, where the best grades of American upland cotton are grown and where the demand is for the best covering available.

[12] The value of bagging received from foreign countries is first separately recorded from bags in 1895.

Imports of cotton bagging from the United Kingdom fall into three classes: 1. New bagging; 2 second-hand bagging; and (3) old bagging suitable only for remanufacture. The English product for the most part is made from a combination of worn bagging and low grades of mill waste.

With her exceptional advantages in the way of raw materials and labor, Calcutta is able to export bagging at a lower figure than Dundee. During the years 1912–1921 the average export prices per square yard of English and Indian bagging were as follows:

TABLE 10.—*Prices per square yard of imported cotton bagging, 1912–1921.*[1]

Fiscal year.	United Kingdom.	British India.	Fiscal year.	United Kingdom.	British India.
	Cents.	*Cents.*		*Cents.*	*Cents.*
1912	6.9	5	1917	10.6	7.4
1913	8.7	5.7	1918	13.3	11.9
1914	7.9	5.2	1919	14.6	11.3
1915	8.1	5.7	1920	13.3	9.4
1916	9.5	6.1	1921	13.2	8.4

Prices of domestic and imported bagging are found on pp. 28–30.

India in the past has not supplied all of our imported bagging, because in contrast to her major lines, burlap, and sacking bags, the American trade in bagging is small and attended with certain risks.[13]

COMPETITIVE CONDITIONS.

Imported bagging constitutes a small part of the material consumed annually in the United States for covering cotton. In the years 1892–1920, the domestic production of raw cotton, including linters, averaged 11,597,000 bales yearly. Allowing 7 yards of material for each bale, 81,179,000 yards of bagging were necessary to cover the American crop; during this period imports averaged 7,728,000 square yards, or 5,796,000 yards of 45-inch material.

The American production of raw cotton and linters during the season 1920 amounted to 13,863,000 bales, requiring about 97,000,000 yards of bagging. Imports of bagging in the twelve months ended December 30, 1920, totaled, 7,261,904 square yards—5,446,000 running yards—or about 6 per cent of all the bagging used for the 1920 crop.[14]

Import statistics are not separately classified to show: (1) New bagging; (2) second-hand bagging, or (3) old bagging that is to serve as raw material for new bagging or is to be rewoven. It is estimated that at least a fourth of the covering material imported in 1920 consisted of bagging, which was subsequently rewoven or mixed with other fibers in the manufacture of new bagging.

Two factors combine to make the volume of imports small—(1) the strong position of the American concerns manufacturing this product, and (2) the risks involved in supplying a demand which fluctuates from year to year.

[13] This subject is treated at greater length on pp. 43, 44.
[14] During the calendar year, 1921, imports were 3,372,000 square yards, valued at $309,397.

The two domestic concerns are the world's largest manufacturers of bagging. Each has a strong and large organization, has been long prominent in this field, and makes a number of products closely allied to bagging, thus saving in overhead expenses.

The import trade is attended with certain risks. The demand for bagging fluctuates from season to season, as it depends upon the size of the crop. Likewise the demand is confined to the period, April–November. Whatever bagging is not sold during this period must be stored until the following season. These factors, together with the uncertainty of bagging remaining on the free list, or being subject to a low rate of duty, have militated against foreign manufacturers concentrating on the production of bagging and against their buying additional machinery.

These considerations have had more influence in limiting imports from Dundee than from India. Calcutta's lack of interest has been due to the small size of the orders involved and the low value of the product, which have offered little incentive to turn from the production of burlap and sacking bags, in which lines the world's consumption up to 1914 was advancing more rapidly than the output.

There is, however, a possibility of India furnishing in the near future a larger part of the American consumption. The first of the two concerns which dominate the domestic trade in bagging, and a subsidiary of the second, are now each building a mill in India for the manufacture of this material. Both companies have already shipped abroad a part of the bagging machinery formerly operated in this country. The subsidiary of the second company was incorporated in 1920 with $5,000,000 capital stock for the purpose of taking over and extending the business of the parent company in India. This subsidiary will also produce burlap.

In the past, although burlap has been subject to a duty which, in the years 1898–1913, ranged between 21 and 30 per cent, over 99 per cent of the domestic consumption was supplied by British India and the United Kingdom. In the fiscal year 1921, the domestic consumption of burlap was about 1,000,000,000 yards, of which about 93 per cent came from India.

The advantages India possesses for the manufacture of jute cloths, and which are responsible for the leading American bagging firms building mills there, will be discussed later.[15]

TARIFF HISTORY.

A study of the paragraphs relating to cotton bagging in tariff acts since 1824, when it was first mentioned, discloses:

(1) That cotton bagging has been assessed at a specific duty in all acts with the exception of those passed in 1846, when it was made dutiable at 20 per cent, and in 1894, and 1913, when it was made free.

(2) That jute has become the leading material used in its manufacture, supplanting flax and hemp.

(3) That in the earlier acts, where the duty was laid on the basis of value per yard, the basis tended to become lower.

---

[15] See pp. 52–54.

The paragraph relating to cotton bagging in the act of 1824 reads as follows:

> On cotton bagging, 3 cents and three-fourths of a cent per square yard.

The first reference to bagging made from jute appears in the act of 1861:

> On cotton bagging or any other manufacture not otherwise provided for, suitable for the uses to which cotton bagging is applied, whether composed in whole or part of hemp, jute, or flax, or any other material, valued at less than 10 cents per square yard, 1½ cents per pound; over 10 cents per square yard, 2 cents per pound.

In 1862, the duty was lowered to three-quarters of a cent per pound on material valued at less than 10 cents per square yard, and to 1 cent on that over 10 cents.

In the act of 1864 gunny cloth, gunny bags, and cotton bagging were assessed at 3 cents per pound, when the value was 10 cents or less per square yard, and at 4 cents when the value was in excess of 10 cents. These products were dutiable in the acts of 1870 and 1883 at 2 cents and 1½ cents, respectively, per pound when valued at 7 cents or less per square yard; and when valued at over 7 cents per square yard at 3 cents in 1870 and at 2 cents in 1883.

In 1890 jute butts were added to the list of materials, from which the cotton bagging might be made. In that act "Bagging for cotton, gunny cloth, and all similar material suitable for covering cotton," if valued at 6 cents or less per square yard, was assessed at 1.6 cents per square yard; and if valued at more than 6 cents per square yard, at 1.8 cents.

The act of 1894 used the same phraseology as the act of 1890, but placed the article on the free list.

The classification adopted in the act of 1897 was a radical departure from former classifications. Paragraph 344 of that act reads as follows:

> Bagging for cotton, gunny cloth, and similar fabrics, suitable for covering cotton composed of single yarns made of jute, jute butts, or hemp, not bleached, dyed, colored, stained, painted, or printed, not exceeding 16 threads to the square inch, counting the warp and filling, and weighing not less than 15 ounces per square yard, six-tenths of 1 cent per square yard.

This paragraph was reenacted without change of wording or duty in the act of 1909, and was made a basis of the classification adopted in 1913. The act of 1913 made cotton bagging free of duty, and while eliminating hemp, which is a soft fiber, from the list of materials from which cotton bagging might be made, added cotton tares and a number of new fibers: Seg, Russian seg, New Zealand tow, Norwegian tow, and aloe.

BAGGING AND COVERING COTTON.

TABLE 11.—*Imports by countries, 1895–1921.*[1]

Rates of duty—cotton bagging—1883–1913.

Act of—	Paragraph.	Tariff classification or description.	Rates of duty, specific and ad valorem.
1883	343	Bagging for cotton, or other manufactures, not specially enumerated or provided for in this act, suitable to the uses for which cotton bagging is applied, composed in whole or in part of hemp, jute, jute butts, flax, gunny bags, gunny cloth, or other material, and valued at 7 cents or less per square yard.	1¼ cents per pound.
		Valued at over 7 cents per square yard	2 cents per pound.
1890	366	Bagging for cotton, gunny cloth, and all similar material suitable for covering cotton, composed in whole or in part of hemp, flax, jute, or jute butts, valued at 6 cents or less per square yard.	1.6 cents per square yard.
		Valued at more than 6 cents per square yard	1.8 cents per square yard.
1894	392½	Bagging for cotton, gunny cloth, and all similar material suitable for covering cotton, composed in whole or in part of hemp, flax, jute, or jute butts.	Free.
1897	344	Bagging for cotton, gunny cloth, and similar fabrics, suitable for covering cotton, composed of single yarns made of jute, jute butts, or hemp, not bleached, dyed, colored, stained, painted, or printed, not exceeding 10 threads to the square inch, counting the warp and filling, and weighing not less than 15 ounces per square yard.	Six-tenths of 1 cent per square yard.
1909	355	.....do.....	Do.
1913	408	Bagging for cotton, gunny cloth, and similar fabrics, suitable for covering cotton, composed of single yarns made of jute, jute butts, seg, Russian seg, New Zealand tow, Norwegian tow, aloe, mill waste, cotton tares, or other material not bleached, dyed, colored, stained, painted, or printed, not exceeding 10 threads to the square inch, counting the warp and filling, and weighing not less than 15 ounces per square yard * * *.	Free.

COURT AND TREASURY DECISIONS.

Pieces of old bagging extensively *used as patchings for cotton bales,* and *bagging as removed from bales*, which might be used as covering or patches for cotton bales, *and jute bagging*, consisting of pieces of old bagging and of sugar bags, cut and torn, classified as waste, at 10 per centum ad valorem under paragraph 479 of the act of 1909 (T. D. 31776, of 1911), were held to be exempt from duty under paragraph 408 of the act of 1913, inasmuch as new bagging for cotton, gunny cloth, and similar fabrics suitable for covering cotton are free thereunder. (T. D. 34207, of 1914.)

* * * *Patches for cotton bales* composed of *single jute yarn* having the word "Paton" stenciled thereon for the purpose of identification

were held to be exempt from duty as bagging for cotton not printed under paragraph 408 and not dutiable as a manufacture of vegetable fiber under paragraph 284, of the act of 1913. (Abstract 40726, of 1917.)

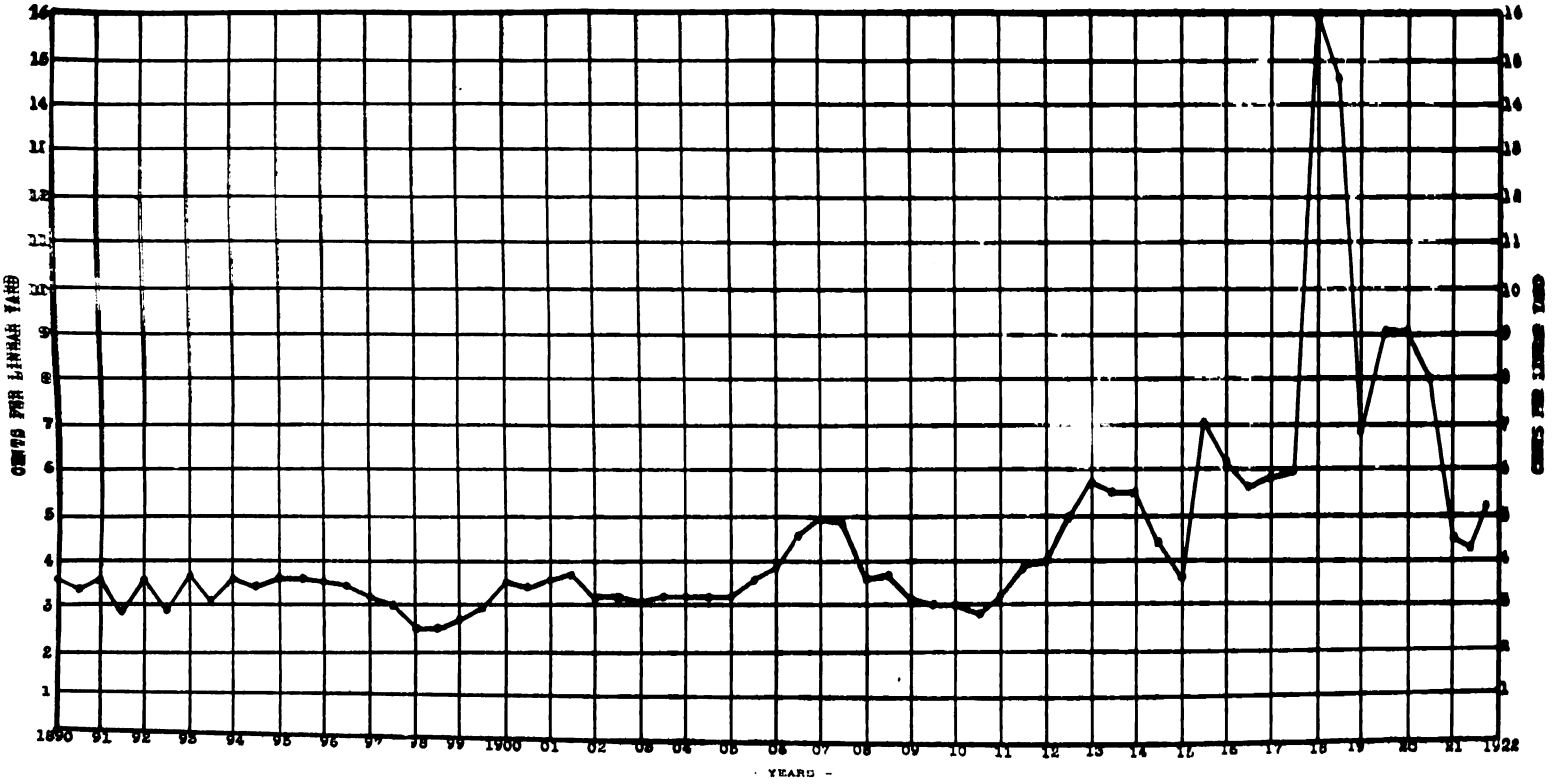
Jute bagging patches, striped and twilled, and not composed of single yarns were held dutiable under paragraph 284 of the act of 1913. (Abstract 39855, of 1916.) . G. A. 8374, T. D. 38506, of 1920. *Cotton patches, whether twill woven or colored, or whether made from plain woven fabrics of single jute yarns,* not colored, were held dutiable under paragraph 384 of the act of 1913, as waste not specially provided for. (G. A. 8374, T. D. 38506, of 1920; modified by McGettrick *v.* United States, 11 Ct. Cust. Appls., of 1921; T. D. 38727.)

Worn bags which have become unavailable for use as bags have not necessarily become unavailable for use as fabrics. Bags which are simply cut down one side and through both ends are no longer bags, but they are still fabrics. If the material is so worn as to be no better than rags, fragments, or shreds, and is not such as is chiefly used for paper making, it is free of duty under paragraph 586, tariff act of 1913, as rags, "not otherwise specially provided for * * *." If it is commercially and chiefly used as paper stock, it is free of duty as such under paragraph 566. If it is no longer commercially suitable for any textile purpose and is not specially provided for as rags or paper stock or under some other more specific designation, it may be classed as a waste under paragraph 384. If it is still a fabric and is "plain woven * * * of single jute yarns * * * not bleached, dyed, colored, stained, printed, or rendered noninflammable * * *," it must be classified as such under paragraph 408. (McGettrick *v.* United States, 11 Ct. Cust. Appls., —; T. D. 38727, of 1921, modifying T. D. 38506, of 1920.)

Secondhand jute sugar bags, twill woven and printed, apparently of whole and sound fabric, with the exception that some of them are sticky with sugar, but which the appraiser reports can be used as containers and which bags are indiscriminately mixed, were held dutiable under paragraph 284, tariff act of 1913 as manufactures of vegetable fiber and not under paragraph 384, or free under paragraph 566. (G. A. 8397; T. D. 38572, of 1920; affirmed in Downing *v.* United States, 11 Ct. Cust. Appls. —; T. D. 38730.)

Chart B—Price 40-inch 10½-ounce Burlap at time of Export from Calcutta, 1890-1921

(*Source:* Prices as of January and July, 1890-1919, and of January, 1920, from "Prices and Wages," Department of Statistics, India. From July, 1920, prices from "Dundee Prices Current." Rupee=32.44 cents.)



PART II.

NONPROCESSED BURLAP.

Description and Uses.

Burlap is the most extensively manufactured of all jute cloths.

The term "burlap" is American, and in a general way refers to all plain woven cloths of single jute yarns. After the weaving operations such cloth may be specially finished but never processed—i. e., bleached, dyed, painted, etc. More specifically, "burlap," unless modified by terms such as "brattice cloth" or "canvas padding," is synonymous with "hessian," which is the English term for plain-woven fabrics of single jute yarns, ranging in weight from 6 to 16 ounces to the linear yard.

Plain-woven fabrics of single jute yarns weighing over 16 ounces to the linear yard are divided into (1) tarpaulin and (2) bagging.

Tarpaulin is used as the basis of water-proofed fabrics of the same name, employed as coverings for hatches, wagons, etc. It differs from burlap in that it is heavier, has more threads to the square inch, and is of a double-warp construction.

Bagging is coarser and more loosely woven than tarpaulin. The best types used in the United States have a double warp. The domestic consumption of double-warp bagging is small compared with that of single warp employed for covering cotton.

Burlap, tarpaulin, and the better grades of bagging have never been distinguished in our tariff acts. Bagging for covering cotton is the only one distinguished from burlap. Trade statistics of foreign Governments do not differentiate between the various types of plain-woven fabrics of single jute yarns.

The term "burlap" as used in this report will include: (1) Burlap, (2) tarpaulin, and (3) double-warp (D. W.) bagging.

The leading use of burlap in the United States, as in all countries, is for sacking and baling. Burlap is made in widths ranging from 27 to 150 inches, and in weight from 6 to 16 ounces to the linear yard. The standard hessian cloth is the 11 porter,[1] 40-inch, 10½-ounce, 12-shot, which is 40 inches wide and weighs 10½ ounces to the running yard. Where the bulk of the demand is for lightweight goods, as in the United States, 40-inch, 8-ounce burlap, 9 porter, 10-shot, may be taken as a standard.

Burlap weighing less than 10 ounces to the linear yard forms the greater part of domestic consumption. A census made by the Department of Commerce in 1918 showed that of the total burlap consumed by 3,473 establishments engaged in some phase of the jute trade, burlap weighing under 10 ounces to the yard constituted 58.3 per cent of consumption in 1917 and 59.1 per cent of the estimated consumption

[1] The porter refers to the reed through which the warp threads pass in the loom, and is the number of splits in the twentieth part of the Scottish ell of 37 inches. The shot is the number of single weft threads per inch.

in 1914 [illegible] abroad, and about as much [illegible] the same result. On that day of the [illegible] were [illegible] per cent consisted of burlap weighing under [illegible] the latter part.

More than [illegible] of the burlap consumed in the United States goes into the manufacture of bags; according to a special study the total burlap used in that country in the calendar years 1914 and 1915 was [illegible] per cent, respectively, of the imports for consumption within the same years.

The leading uses of burlap in the United States are as containers for farm and [illegible] products, such as cotton, fertilizer, flour, sugar, and vegetables. The smaller bags are manufactured from burlap weighing less than [illegible] ounces to the yard. [illegible] census taken in 1914 shows that of the [illegible] bags made of burlap in 1917, 174,000,000 had been manufactured from materials under 10 ounces to the yard, and of the [illegible] estimated for 1918, about 185,000,000 from burlap weighing less than [illegible] ounces.

Millions of yards of burlap are used for baling and wrapping a great variety of products. It constitutes the bulk of burlap as a covering for cotton cloth shipped in bales. One of the largest manufacturers of cotton fabrics stated that it [illegible] before the war when the price was reasonable now we have ample facilities of burlap but the price advanced during the war to a prohibitive point and we were forced to manufacture a substitute which we made by using certain grades of our waste, and we found the substitute approximately satisfactory and much more economical. Now that the price is coming down to a more reasonable point we, of course, can use more of it.[1]

Next to its use for bags and for wrapping and baling purposes, burlap is most extensively employed as a backing for linoleum and floor cloths. In 1914 and 1915, linoleum and floor cloth factories, according to census reports, consumed 42,000,000 and 33,133,000 square yards of burlap respectively. The figure for 1914 is low owing to the high price and scarcity of linoleum burlap and to the substitution of floor coverings made of felt paper.

The leading sizes and weights of burlap used as a foundation for linoleum are—

[illegible] ounces to the square yard.
[illegible] ounces to the square yard.
[illegible] ounces to the square yard.
[illegible] ounces to the square yard.

[illegible] of consumption comes the roofing industry. One [illegible] of roofing products states that he uses yearly about [illegible] yards, the bulk of which consists of the 40-inch width, [illegible] ounces to the linear yard.

[illegible] PADDING, BUCKRAM, AND WEBBING.

[illegible] purposes for which burlap is employed are its use [illegible] as stiffening for keeping garments in shape.

[illegible]

[illegible] See also p. 11. A reprint of this report is [illegible] S. Doc. 436.

[illegible] p. 38.

in furniture for separating the springs from the stuffing, and for horse clothing. The material used by the tailoring and upholstering trades is commonly made from lightweight burlap of close weave and is distinguished from the general run of burlap by the term "jute canvas."

Imports of jute canvas prior to 1914 accounted for about 3 per cent of the domestic consumption of burlap. The best grades of jute canvas are used as interlinings in coats and are known as tailors' padding or canvas padding. Paddings vary in width from 20 to 24 inches, and in weight from 4½ to 6½ ounces to the linear yard.[5] About one linear yard is used in a coat.

Fabrics of flax constitute the bulk of consumption,[6] and because of their stiffness, strength, and evenness, are most suitable for padding purposes. Since 1914 there has been a marked increase in the domestic consumption of low grade paddings made of all jute as well as those made of a mixture of jute and cotton. The construction of these paddings may be judged from the following table giving the specifications of interlinings used in the manufacture of Army clothing.[7]

TABLE 17.—*Constructions of jute canvas padding.*

Material.		Minimum weight in ounces per linear yard.	Minimum threads per inch.		Minimum tensile strength.		Width.
Warp.	Filling.		Warp.	Filling.	Warp.	Filling.	
					Pounds.	*Pounds.*	*Inches.*
Jute	Jute	6	20	24	100	85	22
Do	do	6 5	18	20	100	85	22
Cotton	do	6	25	25	50	85	22

In the act of 1913 paddings are subject to varying rates of duty, according to the materials from which made. Those of all linen or of a mixture of linen and other fibers, with linen as constituent of chief value are dutiable at 30 per cent under paragraph 283; those of jute and cotton or any other mixture in which jute or any other vegetable fiber other than cotton or flax is the component of chief value are assessed at 35 per cent under paragraph 284;[8] and those of all jute are free of duty under paragraph 408.

Closely related to padding is buckram, which is a coarse-woven fabric of cotton or jute stiffened with glue or with starch. Jute buckram, made by subjecting burlap to the process of sizing with starch or glue and then running the material through heavy rollers, finds its greatest use as a body for hats and bonnets. It has been held that the starching or sizing of burlap does not exclude it from the provisions of paragraph 408.[9] Buckram which has been dyed, principally black, is occasionally imported and pays a duty of 10 per cent under paragraph 279. One of the largest bag companies uses from 1,250,000 to 1,500,000 yards of burlap yearly in the manufacture of this article, about two-thirds of which consist of 8-ounce burlap and one-third of 10-ounce.

[5] The construction of a number of paddings of different fibers is given on pp. 64, 65.
[6] A domestic manufacturer of canvas padding estimates that the annual domestic consumption of tailors' padding of all materials is about 50,000,000 yards. (Ways and Means tariff hearings, 1921, p. 2519.)
[7] War Department specification No. 415-4-1249—1919.
[8] T. D. (Abstract) 37515.
[9] T. D. 20611.

Narrow woven fabrics of jute not exceeding 12 inches in width, commonly known as webbings, are used for making bands, belts, etc. In 1919 there were 30,856,000 linear yards of webbing produced in the United States, the greater part of which was made from yarn averaging about 9 pounds.[10] One manufacturer, who specializes in weaving webbing for the upholstery and automobile trades, uses the following jute yarns: 7-pound 2 ply, 14 pounds, 10-pound 2 ply, 16 pounds, and 18 pounds. Three webbings are commonly woven on one loom. Webbings of jute or of any vegetable fiber are specifically provided for in paragraph 262 of the act of 1913, at 25 per cent.[11]

SUBSTITUTES.

No domestic product serves as a satisfactory substitute for burlap. Cotton cloth is its nearest competitor. Its substitution is limited, because burlap possesses a strength which can not be obtained in cotton cloth except at a price much higher than that commonly asked for burlap. Burlap and cotton cloths are each so particularly adapted for certain purposes—burlap for sacking commodities that demand strength of texture rather than closeness of weave, and cotton for sacking pulverized and ground products—that substitution is limited and confined to periods when the price of one is abnormally high in terms of the other. For example, cotton cloth has been substituted for burlap in containers for bran, feed, and similar products, or in recent years, heavy burlap has been substituted for cotton in carriers for cement.

Although jute is weaker in tensile strength than cotton,[12] the difference in strength is not commensurate with the marked difference ordinarily existing in the price of the raw fibers. Cotton sheeting 40 inches wide, 4.25 yards to the pound, and burlap 40 inches wide, 7½ ounces, are standard fabrics, and in any substitution would be interchanged. Expressed in equivalent terms of weight, the cotton cloth weighs 3¾ ounces and the burlap 7½ ounces. The wholesale price in New York, January 1, 1922, of the 40-inch sheeting was 8.75 cents per linear yard and of imported 40-inch burlap, 4.25 cents per linear yard. Thus, while the burlap possessed twice the weight of the cotton cloth, its price was less than one-half.

Burlap bags are cheaper, and because of their greater strength, are superior to cotton bags for sacking heavy commodities such as grain, produce, fertilizer and other rough and bulky commodities. Burlap bags are inferior to cotton bags (1) for small packages; (2) for purposes where possibly the lint of the burlap might affect the contents, such as foodstuffs; (3) where a close woven fabric is required, as for sacking flour, and (4) where the bag is to receive an elaborate trade-mark.

In the past certain manufacturers have stated that burlap has competed with the manufacture of the lowest grades of cotton cloth,

[10] The number or count of jute yarn is stated in terms of the weight (in pounds) of a length of 14,400 yards, which is known as a "spyndle."

[11] T. D. 16652.

[12] Matthews in his Textile Fibers, p. 253, gives the breaking length in kilometers of cotton yarn as 13–14 and of jute yarn 9.9; of cotton thread as 25, and of jute thread as 20.

particularly of osnaburg, a cloth made partly of cotton waste and extensively employed in the production of cement bags.[13]

DOMESTIC PRODUCTION.

The domestic production of burlap and of paddings of all jute, or with jute as chief value, has always been negligible, and with the exception of three mills operated during the war, has been confined to companies that have woven such cloth as a subsidiary part of their business. The output of burlap and of paddings was greatest in 1918–1920. The production of burlap amounted to 7,292,000 linear yards in 1918, to 5,659,580 yards in 1919, and to 4,879,642 yards in 1920. The output of paddings was 8,540,000 linear yards in 1918, 4,200,000 yards in 1919, and 4,150,000 yards in 1920. The domestic consumption of burlap and of all-jute paddings in the same years was between 800,000,000 and 1,000,000,000 yards.

EQUIPMENT.

Machinery for weaving and finishing jute cloths has been standardized. Dundee is the world's greatest manufacturing center for such machinery. Before the war India obtained its jute machinery from Dundee. Since the war, however, the Calcutta industry has begun to manufacture its machinery on a small scale.

METHODS OF PRODUCTION.

The successive steps in the manufacture of burlap may be indicated by naming the processes and the machinery used from the time the raw jute is brought into the factory until the finished cloth is shipped in bales:

Batching: Jute opener, softener.

Preparing: Breaker card, finisher card, first drawing frame, second drawing frame, roving frame.

Spinning: Spinning frame.

Yarn preparation: Cop-winder machine (for weft), drum-winder machine (for warp), dressing machine, drawing-in (handwork).

Weaving: Loom.

Finishing: Cropping machine, damping machine, calendering or mangling machine, inspecting and folding machine.

GEOGRAPHICAL LOCATION.

By far the greater part of the domestic production of burlap in recent years has been the output of factories located in the eastern

[13] A prominent bag company, located in the Middle West, which produces about twice as many cotton bags as burlap bags, late in 1920 wrote as follows:

"In reference to the competition between cotton and burlap bags, cotton bags have an established preference for certain commodities, such as flour, cement, etc., while burlap is used practically as a standard for feed, fertilizer, and kindred products, and substitution of burlap for cotton, where cotton is standard, happens only in cases where the differential between cotton and burlap is abnormally great. Cotton sheeting or cotton osnaburg bags are standard for cement, and the only substitution to any marked degree that we know of was during last year when 30-inch 7-ounce osnaburg cost 25 to 30 cents a yard, as compared with 10 cents a yard now, and 33-inch 10-ounce burlap, which was used as a substitute, was selling at about 17 cents a yard, as compared with about 6 cents a yard now. In other words, when five-sixths of a square yard of the cotton material was worth 13 cents more than a square yard of burlap, added to the difficulty in securing sufficient supplies of cotton, the incentive for substitution was abnormal and should not be taken into consideration. We believe the same situation is relatively true that the competition of burlap and cotton is to a considerable extent a matter of the natural adaptability of the materials for the purposes required."

east of the United States. Of the eight mills that have woven burlap or paddings of all jute, or of jute and cotton, since 1914, two each are located in Massachusetts and New Jersey, and one each in New Hampshire, New York, Pennsylvania, and California.

PRODUCTION.

In comparison with the domestic production of jute yarn and jute cloth, for covering cotton, in which lines the American manufacturer is dominant in his home market, the domestic output of burlap is insignificant, normally less than 1 per cent of the consumption. In 1913 there was only one firm making burlap for sale. This firm, located on the Pacific coast, writing as of November, 1920, says:

> We are the only manufacturers of burlap but practically discontinued the manufacture of same in 1914. * * * The value of the jute looms scrapped in 1914 was about $3,000.

Another mill, which was originally built for the manufacture of burlap and which makes jute twine and cordage its principal products and weaves jute bags on a small scale for a firm manufacturing chemical products, previous to the war wove some burlap for wrapping its own shipments.

The war gave a decided impetus to the production of burlap, principally for paddings in coats and as a base for linoleum. In 1915, following the curtailment of imports of paddings, a domestic mill began weaving canvas padding of flax, jute, and cotton, made in widths ranging from 20 to 27 inches to the linear yard, and in weight from 5 to 12 ounces to the square yard. The production by this mill increased steadily from 1,000,000 yards in 1915 to 3,500,000 yards in 1920. Nine-tenths of the total output consisted of material woven with a cotton warp, with jute as the filling and constituent of chief value. During 1918 this mill also turned out about 3,000,000 yards of 22-inch 6.7-ounce material to serve as interlinings in Army clothing. In 1919 it wove 100,000 yards of jute and cotton tapestry and upholstery ranging from 36 to 54 inches in width and averaging about 15 ounces to the square yard. The jute yarn used by this company ranged from 3½ to 14 pounds and was bought of domestic manufacturers. The looms were designed by an American concern. Since the close of the war this mill has temporarily ceased its manufacture of paddings made from all-jute yarn. It has, however, continued weaving paddings of jute and cotton.

In 1918 two other mills began weaving tailors' paddings of jute and cotton. The total yardage woven by the first in the years 1918–1920 amounted to 3,300,000 linear yards, and of the second about 590,000 linear yards. The first company reports that it was forced to discontinue making such goods in July, 1920, because it could not compete with foreign prices. The mill of the second company was not in operation during 1921. The leading yarns used by the companies were 3½-pound, 4-pound, and 5-pound jute, and 20/2, 14/1, and 30/2 cotton, all supplied by domestic manufacturers.

The company which in prewar years had woven small quantities of burlap for baling its shipments of yarn and twine also pro-

duced during the war paddings of all jute for use as interlinings in Army clothing. The maximum annual production was 1,000,000 yards of 6-ounce padding. This company also arranged that four carpet mills should weave burlap from yarn furnished them. The greatest quantity for any one year woven by the carpet mills was 2,000,000 yards, consisting of 8, 10, and 16 ounce burlap. With the close of the war this mill ceased weaving burlap, finding it cheaper to buy than to manufacture its wrapping materials.

During 1917 and 1918 another company which specializes in the manufacture of jute yarns, twines, and bagging, was induced to weave burlap. In writing of its production, this company states:

* * * The demand for burlaps during the earlier years of the war not only created such an acute shortage of same in this country during the latter part of 1916 and 1917, but created an artificial price level that enabled a manufacturer here to compete with the Calcutta labor market.

At the request of the United States Government, which during 1917 and 1918 was badly in need of bale coverings for overseas goods, we installed a small unit of looms to help the situation out, and these we ran about a year and a half, until the signing of the armistice, together with the making of a fixed price on burlaps at a level which it was impossible for us to compete, made it no longer either necessary or possible for us to run our looms.

Following the embargo placed in 1918 upon exports of jute products from Dundee—the leading source of burlap used as backing for linoleum—two American companies which specialize in the manufacture of linoleum began weaving burlap on a small scale for consumption in their factories.

The first company started producing in October, 1918, and discontinued at the end of May, 1921; the second began in June, 1919, and ended in December, 1920. Their combined output from October, 1918, to May, 1921, amounted to about one-tenth of the burlap used annually in the United States as a foundation for linoleum. All but a small part of that woven consisted of 72 and 144 inch widths.

Foreign Production.

BRITISH INDIA.

India, the world's leading manufacturer of jute goods.—Calcutta, in the Province of Bengal, is the world's largest manufacturer and exporter of jute products. Almost all of the large mills—70 out of a total of 74 in 1917—were situated in the Province of Bengal. These 70 mills employed more than 99 per cent of all the operatives in the jute industry of India.[14]

Under ordinary conditions Calcutta consumes more than half of all the jute grown in the world. During the season July, 1919–June, 1920, the consumption of the Indian mills amounted to 5,227,000 bales of 400 pounds each, as against actual exports of 3,400,000 bales. Of her total jute manufactures she exports about 60 per cent, which in turn represents about 52 per cent of the world's total production of gunnies. In contrast, the United Kingdom, which ranks next in the manufacture of jute goods, exports about 40 per cent of its total production, about 12.5 per cent of the world's output.

[14] "Large Industrial Establishments in India," Calcutta, 1920, p. ii, introductory note.

Importance of the jute trade to India.—In numbers employed the jute industry in 1917 held second place among India's industries. In that year it was surpassed only by mills spinning and weaving cotton, which, numbering 284, employed an average of 282,297 hands daily. Close behind was the jute industry with 75 mills and 262,100 operatives. In March, 1920, according to official British statistics, there were 76 jute mills, with 41,045 looms and 855,307 spindles. The number of operatives was 280,408.

In the Indian fiscal year, 1921, shipments of raw and manufactured jute, with a combined value of $224,869,100 ranked first in point of value of Indian goods exported and constituted 29 per cent of all the Indian merchandise shipped abroad. Their value in the preceding year was $142,373,100, or 24 per cent of the total. Shipments of raw cotton and its manufactures, which ranked in 1920 held first place in value of Indian merchandise sent overseas, yielded this position in 1921 to raw jute and gunnies, i. e., manufactures of jute. In 7 of the 30 years previous to 1921 shipments of raw and manufactured jute have been India's chief article of export.

During the war a decided decline in shipments of raw jute was more than offset by a marked advance in exports of jute manufactures, principally bags and cloth, which increased from an average of 9 per cent of all merchandise exported in 1911–1914 to 22 per cent in 1919, thus rising to first place in value among India's exports. In the period 1911–1914 exports of jute manufactures averaged 646,100,000 yards, with an annual value of $60,000,000, as compared with 714,500,000 yards in the fiscal year 1919, with a value of $135,000,000, with 881,900,000 yards in 1919, valued at $177,000,000, with 643,000,000 yards in 1920, valued at $111,000,000, and with 820,000,000 yards, with a value of $177,000,000, in the year ended March 31, 1921.[1]

The value of raw jute and jute bags sent abroad in 1920 accounted for 14 per cent of all the Indian merchandise exported, and in 1921, 22 per cent. In the former year raw jute was the chief item of export trade, jute manufactures in point of value. This position, however, was reversed in 1921.

Before the war shipments of gunnies made up more than half of the value of exported articles, while raw jute accounted for [illegible] per cent of the total, and in 1920–21 for 9 per cent.

[illegible]—The dominant position of India's jute industry is the result of a steady and rapid growth that has few parallels in the annals of [illegible]. About 1850 the manufacture of jute goods was first started in a primitive way in India by settlers from Scotland, using the jute machinery and methods in Dundee. Since that time the Indian industry has shown [illegible]. According to [illegible] in 1884 [illegible] and that [illegible] in 1914 [illegible] the result of [illegible] in 1914 [illegible] and 80,000 in 1920, the years ended March, 1914 and 1920.

---

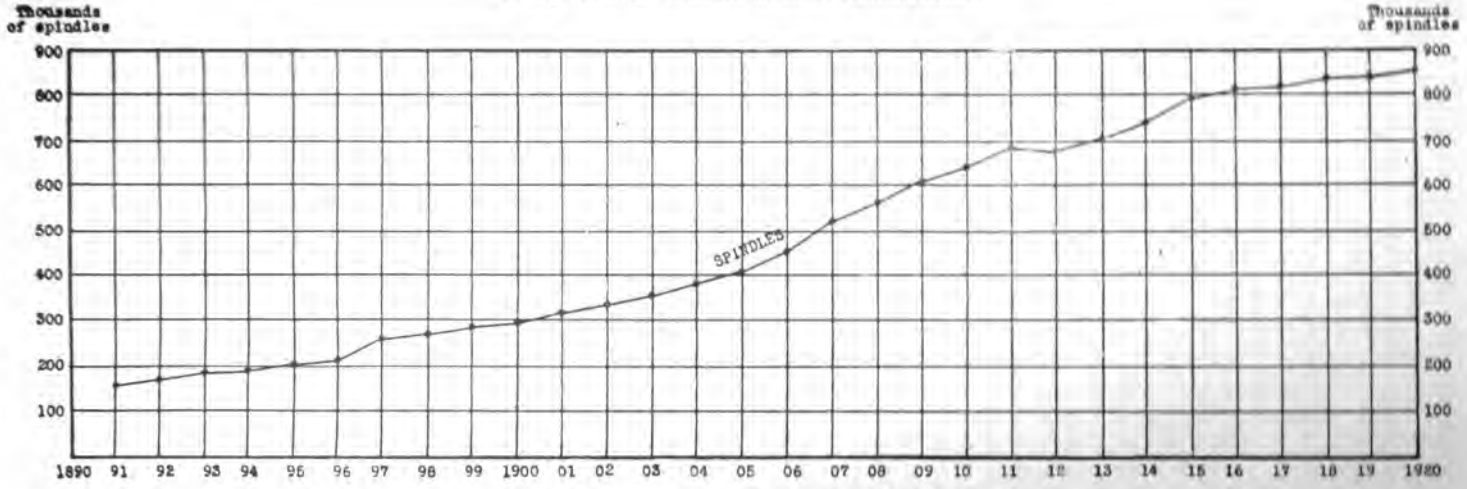
[2] [illegible]
[3] [illegible]

CHART C.—Spindles in Indian Jute Industry, 1891-1920.

(*Source*: Statistical Abstracts Relating to British India.)



More striking has been the increase, particularly since 1900, in the number of spindles working on jute products. In the period 1880–1900 they advanced fourfold, from 70,840 in 1880 to 295,302 in 1900. The ratio of increase was slightly less during the interval 1900–1920, when their number advanced steadily, with the exception of 1912, to a total of 855,307 in 1920.

Keeping pace with increases in spindleage and loomage the number of hands engaged by the jute mills in 1880–1900 also advanced about fourfold, from about 27,000 to 102,000. In 1911 the operatives numbered 216,390, and in 1920, 280,408.

The dividends returned by the mills indicate that the industry is profitable. Of 35 mills publishing financial statements for their fiscal year 1912, 6 reported no dividends and 29 an average of 12.5 per cent; and of 37 in 1914, 9 announced no profits, and 28 an average of 14.6 per cent each. Two companies returning extra large dividends for 1914, one of 110 per cent and the second of 55 per cent, account for the 1914 average being in excess of 1912. The war period was one of unprecedented prosperity for the Indian industry; 42 companies returned dividends for 1918 averaging 145 per cent. The close of the war was not followed by any marked decline in profits. For their fiscal year 1919, 42 companies announced dividends averaging 131 per cent per mill, and for 1920, 134 per cent.[18]

At the close of the war, Calcutta prepared for the greatest expansion in its career. In January, 1920, 14 new mills were in course of construction.[19] It is estimated that the total loomage of these mills, combined with the extensions planned by the mills then in operation, amounted to a 20 per cent increase in weaving capacity.

By January, 1921, only 1 of the 14 mills had been completed. The projects for two others had been abandoned. A number of factors retarded the anticipated expansion, the foremost of which was the depression in late 1920 in trade the world over, which cut down materially the demand for gunnies, and caused production to run far ahead of consumption. Accompanying the decline in demand was a sharp break in prices. The 40-inch, 10½-ounce burlap was selling in Calcutta for 4.98 cents a yard in December, 1920, and for 4.21 cents per yard in June, 1921, as compared with 5.51 cents in January, 1914, and 9.08 cents in January, 1920.[20]

The latest official figures available regarding Indian weaving capacity are those showing the looms in existence in early 1920. At that time there were 41,045 looms turning out gunny cloth, as compared with 36,050 in 1914 and 31,418 in 1910. Private sources give the total on January 1, 1921, as 40,898, and on January 1, 1920, as 40,447.[21]

---

[18] The profits returned by individual jute mills for each of the years 1912–1920 is shown on pp. 78, 79.

[19] "Indian Jute Mills and Their Looms," on Jan. 1, 1920, published by Moran & Co., brokers, Calcutta, India.

[20] Rupee=32.44 cents.

[21] Statistics other than those of the Indian Government are taken from "Indian Jute Mills and Their Looms," published annually on Jan. 1 by Moran & Co.

The number of jute looms in India since 1890, as given by official and private sources, follows

TABLE 18.—*Jute looms in India, 1890–1921.*

Year	Number given by official source [1]	Jan. 1—	Number given by private source [2]
[illegible]	4,204	1890	7,964
[illegible]	14,119	1900	15,536

[illegible]		1921	[3] 29,398

[1] [illegible] showing the date when the yearly census was taken, or whether the figures [illegible] in operation.

[2] [illegible] Statistics of British India," published by Moran & Co.

[3] [illegible] Journal," Calcutta, of Jan. 14, 1921, states: "On the 1st of January, 1915, there [illegible] looms working. On the 1st of January 1919, this number had increased to 39,451, which had [illegible] the 1st of January, 1920, to 40,407, and during 1920 about 2,000 additional looms have [illegible]."

Number of sacking and hessian looms. The number of looms for turning out twilled cloth installed between January 1, 1919, and January 1, 1921, was 370, and those for weaving burlap, 1,077.[22] A greater number of new looms would have been added but for labor trouble during 1920 in Scotland, which supplies practically all the machinery.

That the number of new hessian looms added since early 1919 is in excess of the new sacking looms is in keeping with the trend of the industry during the past 10 years. In 1890 sacking looms totaled 6,500, and burlap looms 1,968. By 1910, the hessian looms had taken the lead with a total of 18,534 as against 13,421 for sacking. At the beginning of 1921 the totals were 16,445 sacking and 24,453 hessian looms.

Comparatively few of the hessian looms are wide enough to turn out backing for use in the manufacture of linoleum. About three-quarters of the hessian looms in January, 1921, had reeds—narrow strips of steel wire to space the warp threads and to keep them parallel—evenly divided ranging between 46 and 52½ inches. On the same date there were 85 looms that had reeds between 78 and 84 inches. Looms with reeds in excess of 84 inches, if any, were [illegible] classified as "other widths," which totaled 483.[23] [illegible] The growth of the Indian industry [illegible] the world's decreasing consumption of jute cloth and [illegible] that Calcutta has [illegible] percentage of her raw material to [illegible] declined. The raw [illegible] 1921 totaled 3,314,158 and [illegible] average of 4,223,000 bales [illegible] 1910–1914.

[illegible] 14,339,000 in 1913, [illegible]

[illegible] Indian Finance Current," Apr.

The demand for jute manufactures has been confined to bags and cloth, for India's exports of yarn and twist never, up to 1913, were small and declining. Only in four years during the period 1900–1913 did the shipments of yarn and twist exceed a million pounds. Previous to the war the largest exports were in 1902, when they totaled 5,221,000 pounds. Beginning with 1907 the quantities of yarn exported declined year by year to 1,741 pounds in 1913. Since that time there has been a marked positive increase. From 317,000 pounds in 1914, the quantity advanced to 3,214,000 pounds in 1918, and then fell back to 1,406,000 pounds for the following year. Exports reached a new level in the 12 months ended March, 1921, when their total was 21,275,781 pounds or 9,494 tons.[25] Shipments in the same time of cloth and bags amounted to 537,424 tons and 467,581 tons, respectively. It is to the close of the war shipments of jute yarn were in large part consigned to Japan and Australia.

Exports of gunny cloth.—Exports of gunny cloth, which classification includes all goods produced from jute, have continued equally with shipments of bags to the present dominating position of the Indian industry.[26] The basis of the present export trade in gunny cloth was laid in the years 1888–1890, when the shipments from India increased from 4,000,000 to 30,000,000 yards. By 1911 exports had jumped to 800,000,000 yards, and they kept increasing by yearly additions of about 400,000,000 yards to 2,280,000,000 yards in 1917. The last part of the war saw a slight falling off from the peak reached in 1917. A twofold increase in the number of gunny bags shipped—principally hessian bags for investment purposes—which rose from 387,000,000 in 1913 to an average of about 780,000,000 bags during the next three years and then declined at the close of the war to 542,000,000, accounts for the decrease in cloth shipped in the fiscal years 1918–1919.

With the close of the war exports of gunny cloth advanced to new levels. For the years ended March 31, 1920, and 1921, the exports were 1,275,124,656 and 1,352,738,649 linear yards, respectively.

Had shipments been limited to actual requirements the aggregate for 1921 would not have surpassed the figure for 1920. The demand for gunnies depends upon the volume of goods to be removed. Notwithstanding the world-wide slump in trade commencing in the last part of 1920, which was followed by a sharp decline in commodity prices, incapacity to pay, and a marked increase in stocks at hand in the largest centers of consumption, Calcutta continued to run her mills on full time and to expand the volume of her shipments. Up to the end of October, 1920, exports of cloth in the past ten months were 35 per cent greater than for the same period in 1919. In the same time there was a gain of 36.6 per cent in the number of bags shipped abroad.

[25] The probability of a further increase in India's shipments of yarn is discussed on page 46.

[26] Exports of gunny bags and cloth, 1900–1922 (rupee=32.4 cents) were as follows:

Fiscal year.	Cloth		Bags	
	Quantity.	Value.	Quantity.	Value.
	Tons.		*Tons.*	
1900		$8,792,704		$31,417,941
1910		27,112,097		72,852,750
1919		80,075,892		53,063,107
1920	337,423	101,044,517	316,832	69,790,869
1921	377,424	92,579,200	465,588	71,860,848
1922 (8 months)	190,808	34,418,085	253,130	31,966,825

In November, 1920, the disparity between the consumption and the production of gunnies became so evident that it was decided to curtail weaving operations. Accordingly, an agreement was entered into by all the mills to reduce during the period January–June, 1920, the working week from six to five days. In March it was agreed to run the mills only four days a week in the months April, May, and June. Later the 4-day week was successively extended through the first part of 1922.

Following this agreement there was a marked decline in shipments. In January–September, 1921, 812,819,000 yards of cloth were sent abroad, a decline of 28 per cent compared with the same months in 1920. Exports of bags likewise fell off, but not in the same degree. There were 345,951,000 bags shipped in the first nine months of 1921, as against 425,764,000 in the corresponding period in 1920.

Percentage of cloth shipments consisting of burlap.—India's shipments of gunny cloth consist almost entirely of (1) hessian, and (2) sacking. Exports of burlap in recent years have formed from 96 to 98 per cent of all the cloth shipped. In contrast exports of bags are usually made up to a very large degree of sacking bags. That India's foreign trade in gunnies is practically limited to hessian cloth and to sacking bags, is explained by the fact that the hessian is shipped abroad for manufacture into sacks, whereas the twilled cloth is retained to be sewed up by Indian operatives. Beginning with 1917, India divided her shipments of gunny cloth and bags according to those consisting of (1) hessian, and (2) of sacking. Exports of hessian cloth amounted in 1920 to 1,233,141,000 yards and in the fiscal year 1921 to 1,318,014,000 yards, and of sacking in the same years to 41,982,000 and 34,724,000 yards, respectively.

Exports of cloth to the United States, 1900–1921.—The United States, India's leading market for hessian and hessian bags, normally receives about two-thirds of all the burlap and about 40 per cent of all the burlap bags shipped. During the fiscal year 1921, 928,392,169 yards, or 70 per cent of all the hessian, and 64,300,000 bags, or 47 per cent of all the hessian bags, were consigned to the United States. As a rule the hessian cloth sewed into bags is equal to about 5 per cent of the cloth shipped as taken from the loom.

Since 1900 shipments of cloth direct from India to the United States have constituted, annually, with the exception of the war years, from 60 to 70 per cent of Calcutta's constantly expanding exports. For instance, gunny cloth consigned to the United States for every fifth year beginning with 1900 has amounted to between 61.1 and 69.9 per cent of all the jute cloth exported from India. In the five years, 1910–1914, the United States received 68.4 per cent of the cloth shipped direct to consuming countries.

The war affected only to a slight degree India's shipments to her leading market. The American consumption of jute cloth of Calcutta manufacture amounted to 56 per cent of the total in 1917 and 58 per cent in 1918. With the restoration of normal conditions, shipments to the United States in the fiscal year 1920 amounted to 64.21 per cent and in 1921 to 68.96 per cent of all the jute cloth sent abroad.

The United States is even a greater consumer of Indian jute cloth than the figures relating to direct shipments from India indicate. In addition, the United States usually consumes more than half of the

value of jute piece goods and bags of foreign and colonial merchandise exported from the United Kingdom. The bulk of this trade consists of Indian jute piece goods. In the years 1910–1914 such goods, showing little variance as regards value, averaged yearly about $8,661,000, of which 57.1 per cent were consigned to the United States.

The extent to which the requirements of the American market have contributed to the growth of India's export trade in gunny cloth is summarized in the following table:

TABLE 19.—*Exports of jute cloth from India to the United States, 1900–1921.*

Fiscal year.	Total to all countries.		To the United States.		Per cent of total quantity.	Per cent of total value.
	Yards.	Value.	Yards.	Value.		
1900	307,021,259	$10,792,704	194,992,909	$5,347,014	63.51	60.81
1905	575,511,587	16,598,322	352,048,890	9,797,510	61.17	59.03
1910	940,101,340	27,349,582	657,432,703	18,190,440	69.93	66.52
1915	1,057,324,125	42,530,339	705,999,139	27,789,910	66.77	65.34
1920	1,275,124,656	101,044,517	818,786,800	62,179,125	64.21	61.54
1921	1,352,738,649	92,579,206	932,956,469	60,657,172	68.96	65.51
1922 (8 months)	742,420,973	31,964,828	524,989,800	23,044,000	70.71	72.09

The amount of sacking cloth shipped to the United States is insignificant. In the period 1917–1921 the largest quantity was 5,250,000 yards, in 1917.

Exports to other countries.—After the United States India's leading markets are Argentina and countries of the British Empire. Shipments to these three markets constitute all but few per cent of India's total exports.

Prices of cloth sent to each country.—As a rule the price per yard of gunny cloth consigned from India to the United States is lower than that sent to the United Kingdom, which in turn pays less for its cloth than the countries of the British Empire. Prices of jute cloth shipped to the United States in 1900, 1905, and 1910 were practically the same, and in each year less than prices to the United Kingdom. The prices to the United States ranged from 2.74 cents to 2.78 cents per yard and to the United Kingdom from 3.16 cents to 3.64 cents per yard. The great demand of the United Kingdom during the war for jute cloth, from which to make sand bags, combined with transportation difficulties, limit the value of any comparisons made during the war. For the years 1920 and 1921 the prices were 7.59 cents and 6.50 cents for the United States as compared with 8.51 cents and 7.61 cents for the United Kingdom.

TABLE 20.—*Average prices of burlap exported from British India.*[1]

[1] Rupee taken at par value of 32.44 cents.

The difference in prices is due to the difference in quality. The burlap sent to the United States is coarser, lighter, and more loosely woven than that shipped to the United Kingdom.[27]

The trend of the Indian industry.—With the jute industry curtailing its production in 1921, and with a number of new mills under construction, it has been suggested that, with the return of normal trade conditions, India's capacity may be in excess of the demand for gunnies, leaving her with a surplus of yarn which will enable her to take a prominent part in a trade in which hitherto she has not figured.[28]

Undoubtedly an output of cloth continuing over a period in excess of requirements will naturally be followed by a curtailment of weaving operations and a determined effort to find markets for yarn not made into cloth. The American home market for jute yarn is large. In 1919 the American production of jute twine (other than binder), jute rope, and sales of jute yarn to carpet mills, totaled 149,684,000 pounds. Dundee's domestic and foreign trade is also large.[29] Exports of yarn in the calendar years 1920 and 1921 from the United Kingdom amounted to 43,549,200 pounds and 27,876,900 pounds, respectively.[30]

Prior to the trade depression, which set in during the last half of 1920, India's facilities for spinning jute yarn were not in advance of the demand for hessian cloth and sacking bags. The records for exports of cloth and bags, the large dividends returned by the mills, and the number of new mills started, testify that trade was brisk and that there was little slack between production and consumption from the close of the war up to late 1920.

With the falling off in the demand for her standard lines, the easiest method for India to dispose of her surplus material would be to ship it in the form of yarn. Curtailed production of gunnies, however, was not followed by an increase in shipments of yarn. The quantity of yarn exported in April–November, 1921, was 1,567,302 pounds as against 7,415,477 and 1,667,952 pounds for the same period in 1920 and 1919. While the quantity exported in the fiscal year 1921 was the largest on record—10,178,785 pounds—it gives little promise of yarn becoming one of India's standard lines.[31]

Several explanations may be offered for the small volume of yarn exported in a time when the Indian industry was facing the greatest depression in its history. The readiest explanation is that running the mills on part time since January, 1921, has brought the production of gunnies[32] into line with consumption, and has cut down the amount of yarn available for export.

Whether, upon the restoration of normal trade conditions and upon the resumption of full time by the mills, exports of yarn will advance, is contingent upon the relation of spindleage to the consumption of hessian cloth and sacking bags. A margin between spindleage and the amount of cloth necessary to fill the world's normal increased

---

[27] For a discussion in detail of the types of burlap imported into the United States from India see p. 51.
[28] Ways and Means tariff hearings, 1921, pp. 2417–2419.
[29] The United Kingdom's trade in jute is shown on p. 80.
[30] Shipments of English jute yarn to the United States in 1919 amounted to 97,200 pounds; in 1920 to 1,782,900 pounds, and in 1921, to 9,308,300 pounds. Total domestic imports of single and plied jute yarns for consumption in the United States in 1919 and 1920 were 62,029 and 2,593,100 pounds, respectively.
[31] Exports of yarn during April–June, 1921, were 236,446 pounds as compared with 3,577,806 pounds, and 711,240 pounds, respectively, for the same periods in 1919 and 1920.
[32] According to the "Dundee Prices Current" of Feb. 15, 1922, Calcutta's exports of hessian cloth for the months January–November, 1921, totaled 1,040,928,842 yards as compared with 1,337,809,614 yards for the corresponding period in 1920.

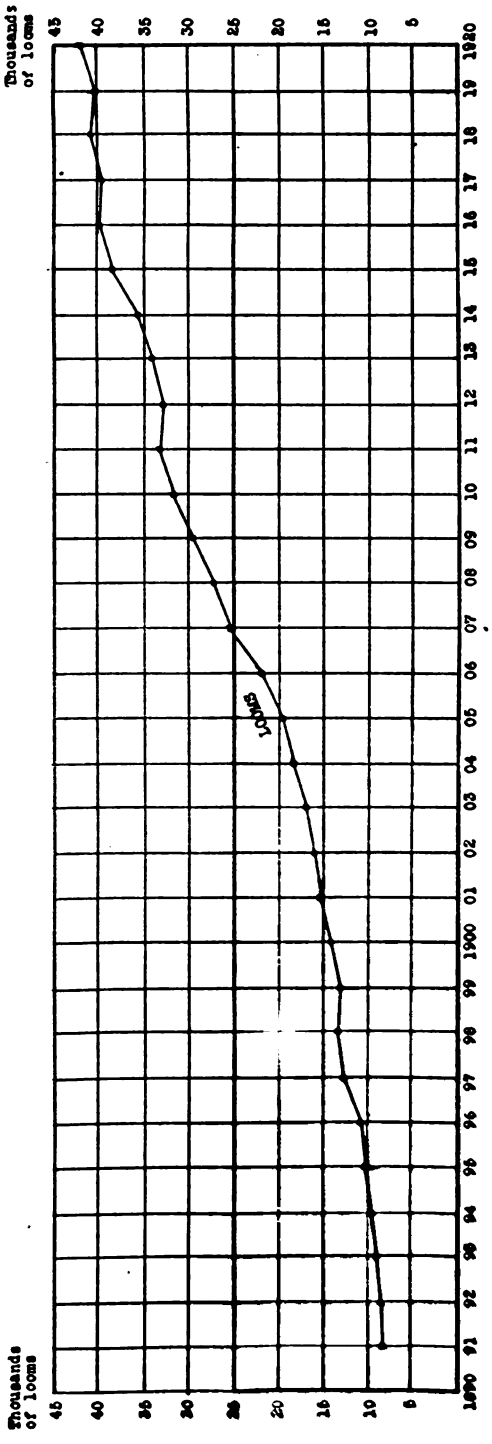

CHART D.—Looms in Indian Jute Industry, 1891–1920.

(*Source:* Statistical Abstracts Relating to British India.)

requirements of hessian cloth and sacking bags will find India greatly expanding her record shipments of yarn in the fiscal year 1921. With the demand for gunnies running ahead of production year by year, as in the prewar period, India will have no surplus yarn for export.

The marked and almost continuous increase in spindleage in the prewar years, and India's concentration on hessian and sacking in the same time, makes spindleage a ready means of estimating the yearly increase in capacity required to enable Calcutta to keep abreast of the world's normal increasing consumption of gunnies. The constant relation of 20 to 21 spindles to a loom[33] makes it possible to translate spindleage into loomage and to determine whether the advance in loomage since the close of the war has been below or in excess of the annual increases in the years 1891–1915.

In only one of the years in the period 1891–1920[34] did the number of Indian spindles fail to show a gain over the total for the previous year. In 20 of the 25 years, 1891–1915, the annual increase ranged between 4.03 and 8.61 per cent.

On the basis of the annual growth in the quarter of the century 1891–1915, an advance of 6 per cent in capacity for each of the years 1920 and 1921 would be normal. This is allowing that the successive increases in spindleage during 1916–1919 of 2.12, 1.46, 1.18, and 0.685 per cent were commensurate with the increased requirements in the same time. On the basis of a 6 per cent[35] increase in capacity for the fiscal years 1920 and 1921, the new looms installed during 1920 would have numbered 2,400 and in 1921 2,500, bringing the total loomage at the end of March, 1921, to about 45,000 looms. The number in existence in early 1920, according to official statistics, was 41,045. That the looms actually added have been less is due in part to the difficulty in securing new machinery and the abnormal trade conditions in late 1920, which brought the work on the new mills and the extensions planned by the old mills to a standstill.

There is little reason for believing that if world trade should become normal in 1921 the demand for cloth and bags from India's customary markets, added to those of the new markets she may win, will reach the point that it will call for the immediate use of 8,000 looms or 20 per cent increase in capacity contemplated in early 1920. More likely the serious depression in the Indian industry in 1921 has put off for years the increases in loomage planned by the older mills and will prove disastrous to a number of newly launched companies,[36] with the result that when trade revives from the slump, which began in 1920, the mills under course of construction will be more in line with the world's normal and advancing consumption of hessian cloth and sacking bags.

DUNDEE.

The rise and decline of the Dundee jute industry.—Dundee, which in 1836 initiated the machine manufacture of jute and which enjoyed a

[33] The number of spindles to a loom in 1891 was 20.02; in 1895, 20.02; in 1900, 20.91; in 1905, 20.46; in 1910, 20.50; and in 1914, 20.64.

[34] The latest official figures available showing the spindleage employed in spinning jute yarn are those for the year 1919–20.

[35] The average annual increase in the years 1891–1918 was 6.23 per cent.

[36] Writing of the outlook of the Dundee textile machinery industry for 1921, the American consul at Dundee, in his annual report for 1920, transmitted Oct. 29, 1921, states: "The outlook for the ensuing year (1921) is not highly encouraging, as a large number of orders for new mills in India have already been canceled or greatly curtailed owing to the unsatisfactory conditions in the jute trade, while delivery of orders has been in many cases indefinitely postponed."

monopoly of the world's production of jute goods in the 20 years following, is to-day second only to India as a manufacturer of jute cloth and bags. It was not until 1856 that the first jute machinery was sent to India, and not until 1861 that the first jute mill was started in continental Europe.

During the half century following the establishment of the industry, the Dundee industry progressed by leaps and bounds, reaching its zenith in the decade 1880–1890. During the following decade, however, it declined to a level which it maintained with difficulty during the following 20 years.

Shipments of jute cloths represent the bulk of Dundee's exports, which are given in English trade statistics under the classification of "jute piece goods" without reference to types of cloths shipped, or whether bleached, dyed, stained, or in any manner processed.

The following table giving the United Kingdom's exports of jute piece goods of domestic manufacture shows the rise, decline, and stationary position of the Scottish industry:

TABLE 21.—*Exports of jute piece goods of English manufacture, 1861–1921.*

Year.	Yards.	Value.[1]	Year.	Yards.	Value.[1]
1861	6,519,252	$618,196	1905	170,383,800	$9,624,648
1870	51,920,808	3,842,866	1910	176,435,800	10,026,290
1880	183,202,400	10,976,405	1915	109,156,000	7,944,609
1890	273,775,900	12,778,626	1920	[2] 149,345,600	32,823,248
1900	173,976,800	9,126,040	1921	[2] 71,635,200	10,496,376

[1] Pounds sterling converted to dollars at £=$4.8665.
[2] Square yards.

In the four years 1910–1913 exports ranged between 149,000,000 and 176,000,000 yards. During the first four years of the war shipments from Dundee fluctuated between 109,000,000 and 134,000,000 yards. Owing to an embargo placed on jute products in 1918, the total fell to 31,594,000 yards. For the years 1919 and 1920 the totals were 111,321,000 linear yards and 149,345,600 square yards, respectively.

The leading reasons for the decline of the Dundee jute industry from the peak reached in 1891, when exports of jute piece goods amounted to 283,618,000 yards, are:

1. The rise of Calcutta as a jute manufacturing center. Not only has the Indian industry wrested from Dundee the dominant position in many neutral and colonial markets, but it has also made serious inroads upon Dundee's home market.

The value of the United Kingdom's imports of jute manufactures, other than cordage, cables, ropes, and twine, advanced from $14,065,000 in 1913 to $30,450,000 in 1919 and to $36,373,000 in 1920. In 1905 India supplied $9,405,000 of a total of $10,131,000 representing imports of jute manufactures other than cordage; in 1910, $11,800,000 of a total set at $15,191,000; and in 1915, about $22,418,000 of the aggregate, $23,395,000. India's competition has forced Dundee to concentrate more and more in the production of specialties, such as fine yarns, figured fabrics, and wide hessians used as a backing for linoleum.

2. The tendency for all nations to become self-sufficient in the manufacture of jute products.

As jute manufactures are comparatively easy to make, there is a tendency to stimulate domestic production by means of high tariffs. Formerly, Germany, Austria, France, and Belgium depended upon Dundee. Long before the war, however, these countries had become independent and were competing with Dundee in neutral markets.

Exports to leading countries.—Dundee's leading markets are the United States, Canada, and Argentina. These countries take not only about 70 per cent of Dundee's exports of jute goods, but about 85 per cent of jute cloths exported from India.

The United States is both Dundee's and Calcutta's best market. In 1900 and 1910 consignments of piece goods to the United States ranged between 49.7 and 57.3 per cent of Dundee's shipments. In the decade 1910–1919 such exports of jute goods from Dundee to her leading market, varying between 40.27 and 59.65 per cent, averaged 49.9 per cent of the total.

Formation of the Jute Industries Limited.—The most recent development in the Dundee jute industry has been the formation of the "Jute Industries Limited," with a nominal capital of $34,550,500. This company plans to operate as spinners, manufacturers and merchants, of cotton, flax, hemp, jute, and wool. By the last part of November, 1920, it had acquired a control of the seven leading jute spinners and manufacturers,[36] employing about 14,000, or one-half of the operatives engaged in the Scottish industry.

IMPORTS.

IMPORTS FOR CONSUMPTION.

Imports of burlap for domestic consumption have increased more than twofold since the beginning of the century. From 1899, the first full year for which statistics on the basis of pounds are available, to 1920 and 1921 advances of 220 and 217 per cent, respectively, were made.

The marked advance in the domestic consumption of burlap since 1899 is shown in the following table:

TABLE 22.—[illegible], 1899–1921.

DOMINANT POSITION HELD BY BRITISH EMPIRE.

In 1920 and 1921, 98.94 and 99.12 per cent of imports came from British India and the United Kingdom. Shipments from India accounted in 1920 for 89.25 per cent and in 1921 for 92.66 per cent of all the hessian imported as against 9.86 and 6.28 for the United Kingdom.

The dominant position held by the British Empire in the American burlap trade is evinced by the record of imports since 1905;[27] by five-year periods, shipments from British territory have constituted from 99.12 to 99.54 per cent of the total quantity.

Since 1905 Indian goods have been forming an ever-increasing percentage of the growing domestic consumption. During the years 1905–1909 India supplied the United States with 81 per cent of its burlap. In the period 1915–1919 the percentage advanced to 89. In the 15 years 1905–1919 such imports rose from a yearly average of about 257,000,000 pounds to 374,000,000 pounds. During the fiscal years ended June 30, 1920 and 1921, India's shipments, totaling 482,932,000 and 497,688,374 pounds, respectively, surpassed all her previous records.

While India has been finding a constantly expanding market in the United States, Dundee's trade has been stationary. Shipments from Dundee averaged 58,672,000 pounds in 1905–1909 and 59,867,000 pounds in 1910–1914, while domestic consumption of English hessian fell to an average of 38,000,000 pounds for each of the years 1915–1919. With the close of the war, Dundee's shipments advanced to their normal level, with a total of 53,402,000 pounds for 1920. Imports of English cloth during the fiscal year 1921 amounted to 33,753,396 pounds, about 80 per cent of which was entered during the first half of the year.

As in the case of cotton bagging, burlap from Dundee commands a higher price than that from Calcutta. Up to 1914 the difference in the prices of Dundee and Calcutta hessians was well-defined; for instance, in the years 1905 and 1910, burlap received from the United Kingdom was quoted at 1.22 and 1.53 cents per pound higher, respectively, than that shipped from India. The relatively higher prices of the Scottish product in recent years is shown in the following table:

TABLE 23.—*Prices per pound[a] of burlap imported into the United States, 1905–1921.*

Fiscal year.	From United Kingdom.	From British India.	Fiscal year.	From United Kingdom.	From British India.
	Cents.	*Cents.*		*Cents.*	*Cents.*
1905	6.38	5.16	1918	19.79	12.80
1910	6.32	4.79	1919	21.01	17.33
1915	9.81	6.69	1920	24.99	15.27
1916	13.19	8.37	1921	21.69	11.17

[a] To convert these prices on the basis of linear yards, 9 ounces may be taken as the average weight of a linear yard.

[27] Quantities of burlap imported according to countries are available beginning with the fiscal year 1905.

TYPES OF CLOTH IMPORTED FROM DUNDEE AND FROM CALCUTTA.

Burlap from Dundee is superior to the Calcutta product. Imports of English manufacture fall into three classes:

1. Heavy weight burlaps which, because of their superior quality and finish, sell for a higher price than those from Calcutta. A large part of the heavy burlap imported from the United Kingdom consists of material of Indian origin, shipped to Dundee where it is given a special finish.

2. Burlaps of extra-wide widths, used in the manufacture of oilcloths and linoleum. One-third of Dundee's loomage, it is estimated, consists of wide looms for the manufacture of linoleum backing.

3. Light-weight burlaps, of extra fine finish such as tailors' padding.

Before the onward march of the Indian industry, Dundee has been forced to yield a constantly increasing part of the American market. To-day Calcutta has entirely supplanted Dundee as a source of materials for bag-making. An inquiry among American bag producers shows that during the years 1914–1919 only one obtained his material from Dundee, and under emergency conditions.

Linoleum burlap and paddings are also imported from Belgium. In the latter line Belgium's competition with the United Kingdom is of a formidable character.

SIZES AND WEIGHTS OF CLOTH IMPORTED.

There are no official statistics giving the sizes and widths of burlap received from each country. Statistics are available, however, for imports for consumption during the years 1897–1913, according to three classes: (1) Fabrics weighing not less than 6 ounces per square yard and not exceeding 30 threads to the square inch, counting warp and filling. This class was further limited during the years 1897–1908 to burlap not greater than 60 inches in width. Previous to 1909, imports for bag-making purposes fell under this heading and after 1909, in addition, burlap of wide widths used as backings for linoleum. (2) Those exceeding 30 and not exceeding 55 threads to the square inch, counting warp and filling. Under this heading fell the best grades of jute canvas imported for use as paddings, for upholstery, horse clothing, and tarpaulins. (3) All other burlaps not specially provided for. This general classification during the years 1897–1913 included all fabrics of extra, no construction, such as those weighing less than 6 ounces to the square yard, and exceeding 55 threads to the square inch, and in addition during 1897–1908, that used by linoleum factories.

The percentages of total imports falling under each of these headings tended to remain the same during the period 1900–1908. Material not exceeding 30 threads to the square inch and that not in excess of 60 inches in width constituted 87.2 and 86.5 per cent of all burlap imported in the years 1900 and 1913. In the same years burlap exceeding 30 and that not over 55 threads to the square inch constituted 4.7 and 3.8 per cent respectively. All other burlaps, chiefly that used by linoleum factories, made up the remaining 8 per cent in 1900 and 9.7 per cent in 1913 of the total quantity.

The elimination of the clause providing that goods under the first part of the specific paragraph could not be greater than 60 inches in width, caused the material ordinarily used for linoleum to come within the provision of the specific paragraph. This change resulted in fabrics exceeding 6 ounces per square yard and not over 30 threads to the square inch composing all but 3 to 4 per cent of total imports in 1910. In the same year, imports of burlap between 31 and 55 threads to the square inch showed a decline to 2.3 per cent of the total, and those not specially provided for fell to 1 per cent of the whole.

Competitive Conditions.

BRITISH INDIA.

Causes for India's dominant position.—The two leading causes for India's position as the world's leading producer and exporter of jute cloths, and the dominant place she holds in the American trade in burlap, are:

1. The production of the world's supply of jute, enabling her to save freight charges.
2. An abundance of cheap but comparatively unskilled labor.

The cultivation of jute is practically confined to India, the amounts grown elsewhere, as in China, Egypt, and East Africa, being negligible. Unsuitable climatic conditions and the lack of cheap labor have so far rendered ineffective attempts to produce it in other countries. Jute is one of India's leading staple crops. The acreage devoted to this fiber averages about 3,000,000, with an annual production of seven to ten million bales of 400 pounds each.

All but a small part is grown in contiguous States, Bengal and Assam. The mills are located upon the banks of the Hoogly, which flows through the heart of the jute-growing section, and forms Calcutta's outlet to the sea. On the Hoogly is transported most of the jute sent to the mills and to Calcutta for shipment overseas.

This concentration of the industry makes it possible for the mills to ship their cloth and bags from Calcutta on practically the same terms as the exporter of raw material, who has to pay the charges for having jute transported to the pressing mills, and then conveyed to the ship. A cubic ton, of 2,240 pounds, of burlap occupies 50 cubic feet; of bags from 50 to 52 cubic feet, and of raw jute from 57 to 62 cubic feet. As the rates are commonly based on space occupied, it costs about 10 per cent less to ship a given weight of gunnies than the same weight of raw material. Shipments of gunnies to the United States from India in the calendar year 1921 amounted to 211,670 tons.

In the case of bagging, however, the small imports of Indian bagging, and the restriction of their consumption to the Mississippi Delta, have made the question of comparative freight charges of little importance in the past. In the fiscal year 1921 the American consumption of Calcutta bagging amounted to 2,764,000 square yards. With the two leading domestic bagging concerns, however, preparing to manufacture bagging in India for the American market, it is likely that imports will increase, and that the use of foreign bagging will become more general throughout the cotton region. These two companies will thus have the advantage in competing with domestic mills located at a distance from centers of consumption.

Labor costs.—The absence of a domestic burlap industry prevents a direct comparison of wages in America and India. The nearest approach to an American industry manufacturing jute cloth is that producing cotton bagging. The classes of workers and the amount of skill required in each line are not the same. Cotton bagging is made from large, rough, jute yarn very loosely woven, whereas burlap is a comparatively fine jute yarn product which has to be carried on a number of processes beyond cotton bagging. An authority who recently visited India, estimates the labor costs of producing burlap as about three times that for the same quantity of cotton bagging.

For the purpose of comparing American and Indian wages, the Commission obtained from four domestic manufacturers of cotton bagging statements of wages paid to employees in their mills during a week in January, 1921. Two of the mills are located in the North and two in the South. The first two manufacture new bagging, the third makes a specialty of new and old patches, and the fourth concentrates its efforts on reweaving old bagging. These mills with one exception returned the data arranged according to: (1) Classes of workers, (2) sex of workers, and (3) the highest wage, (4) the lowest wage, and (5) the average weekly wages paid to each class of operatives.

The wages paid to corresponding classes of American operatives, as submitted by four domestic mills, and of operatives in a jute mill of Bengal as published by the Indian Government, are as follows:

TABLE 24.—*Weekly wages paid to Indian and American jute operatives.*

Class of workers.	Average wages paid in a jute mill in Bengal, January, 1920.	Average wages paid in American cotton bagging mills in January, 1921.	Class of workers.	Average wages paid in a jute mill in Bengal, January, 1920.	Average wages paid in American cotton bagging mills in January, 1921.
Carder	$0.89	$14.65	Winder	$1.91	$13.60
Rover	1.75	18.60	Weaver	2.84	19.50

The average weekly wages paid to seven classes of workers employed in the Indian jute mill shown in Table 24 amounted to $1.33 per worker in January, 1919, and $1.69 in January, 1920.[38]

The wages paid to American operatives were on the basis of a 48 to 55 hour week. By the terms of the Indian factory act passed in 1912, 12 hours constitute a day's labor. The number of hours actually worked by the Indian operative is between 9 and 10.

The data relating to the wages paid to American and Indian jute operatives would be misleading if used as the basis of comparative labor costs, as the efficiency of the Indian operative is below that of the American. The most authoritative and recent statement regarding the efficiency of Indian labor is to be found in the report of the "Indian Industrial Commission," published in 1919. On the question of the relative efficiency of Indian and western labor and the causes underlying the comparative inefficiency of the former, this

[38] The wages paid to nine classes of operatives in an Indian jute mill, 1900–1920, are shown on p. 77.

report states: "Indian labor in organized industries is much less efficient than the corresponding classes of labor in western countries; and there is evidence to show that in many cases it does not produce as cheaply as western labor in spite of its lower wages. It is true that inferior physique and tropical conditions contribute to this state of affairs; but there is grave reason to believe that the former is to some extent the result of preventable disease, whilst other causes, which are even more obviously remediable, are factors that unnecessarily increase the difficulties of our labor problem.

"All authorities who are qualified to speak on the subject agree that Indian labor is content with a very low standard of comfort. This secured, the Indian workman, generally speaking, takes advantage of the greater earning power given to him by increased wages to do less work, and shows no desire to earn more money by working more regularly or by improving his own efficiency. In the case of Bombay, witnesses have stated that since the 10 per cent rise in the wages of mill operatives given during the rains of 1917, there has been an actual falling off in output." [39]

Through the employment of Scotch overseers, who have had actual experience in Dundee mills, and through the use of the best and most up-to-date machinery, the jute industry is run at a level of efficiency that is very high for India. Calcutta possesses the finest machinery available for making jute products. A number of mills generate their own electric power. As a rule, the mills are self-contained in that they take in the raw material and turn out the finished product in bales.

UNITED KINGDOM.

As compared with the American producer, the Dundee manufacturer has two advantages:

1. The skill which comes from being long established in this field. Dundee's workers are so skilled that her goods are preferred where quality of cloth and weaving are the leading considerations. Notwithstanding India's import duty of 7½ per cent on jute manufactures, the United Kingdom supplied her with fine jute goods valued in the Indian fiscal year, 1920, at $769,469, and in 1921 at $729,566. English goods consisting chiefly of fine bags and canvas, accounted for about 90 per cent of the total in these years; Japan furnished the remainder. India's total imports of jute goods in the prewar year were valued at $843,440.

2. Lower labor costs.

January, 1921, was a period of marked depression in the Scottish jute trade. Employment conditions were very poor. Ninety per cent of the operatives were working on an average of 23 hours per week less than full time. In contrast, in January, 1920, trade was very brisk and there was a shortage of help. Therefore, the wages in the latter period are given.

TARIFF CONSIDERATIONS.

OPINIONS OF TRADE REGARDING DUTY ON BURLAP.

Expressions of opinion regarding changes in duties on burlap show an agreement on the part of trade that such duties, unless very high, would be for revenue purposes only. For instance, an American domestic bag company, with factories in various parts of the country, writing in November 1920, says:

> The question of protection to home industry does not arise, as there is no home industry to protect and there can not well be any. The question of adequacy or inadequacy of the duties, therefore, is to be considered from the standpoint of tariff for revenue only.

This is largely in accord with the position taken by another bag factory with headquarters in the central part of the country. This company, whose output of cotton bags is greatly in excess of those made of burlap, stated its opinion in December, 1920, as follows:

> Concerning the adequacy or inadequacy of duties now in force on burlap, considering the fact that burlap is primarily a raw material imported for the purpose of converting into bags or other products in this county, it seems to us that plain burlaps not processed should, from the standpoint of industrial protection only, be admitted free as at present.

An American manufacturer of linoleum, who during the war erected a mill and produced burlap, is of the opinion that a duty high enough to cover the difference between the costs under American and foreign conditions, would impose a very heavy burden upon all consumers. In this connection, he continues:

> Our impression is that the people of the country as a whole will be served better by having burlap continued on the free list. The only way a duty on burlap might be justified would be as a revenue measure.

DUTY NECESSARY TO PROMOTE DOMESTIC INDUSTRY.

A domestic firm, which manufactures a jute product kindred to burlap, in reporting that it does not manufacture this type of jute cloth, adds:

> * * * There is practically no burlap made in the United States, owing to an inadequate tariff to either foster or protect the industry. Based on present (early 1921) wages and other conditions, we should estimate a duty of about 5 cents per square yard would be needed to establish the burlap industry in this country. Anything less than this would be tariff for revenue.

On December 28, 1921, 40-inch 10½-ounce burlap was being offered wholesale in New York at 5.20 cents per linear yard.

BURLAP AS A SOURCE OF REVENUE.

Imports of burlap in the gray exceed in value imports of any other textile fabric or manufacture. Their value is about equal to the combined value of total imports of countable cotton cloth, and of all the manufactures of wool listed under Schedule K. In the 12 months ended June 30, 1914, imports of burlap were valued at $44,827,000, as compared with $11,523,000 for cotton cloth, and with $33,579,000 for wool fabrics and manufactures entered in the same time. In the calendar year 1920, imports of these items were valued as follows: Burlap, $88,896,000; countable cotton cloth, $44,913,000; and all wool manufactures, $51,433,000.

A duty on burlap has been an important source of revenue in the past. In the years 1897–1913, when this fabric was dutiable, the total revenue obtained from burlap, both specified and nonspecified, showed a marked tendency to increase. Ranging between $2,496,000 in 1899 and $7,676,000 in 1913, the total in these years averaged $4,772,000 annually. In the years 1897–1913 the equivalent ad valorem duty on all classes of burlap averaged 26.75 per cent, while the specific duty was about 1.65 cents per pound, or about 1 cent per linear yard.

The acts of 1899 and 1909 divided imports of burlap, on the basis of weight and thread construction, into three classes. The first class included the burlap commonly used for sacking and baling purposes. The duty imposed on this type by the act of 1897 was five-eighths of 1 cent per pound and 15 per cent ad valorem, and by the act of 1909, nine-sixteenths of 1 cent per pound and 15 per cent ad valorem. The equivalent ad valorem of this compound duty, varying between 29.25 and 21.35, averaged 25.68 per cent. The average value of burlap imported under this heading was 5.95 cents per pound.

The second class embraced burlap of extra light weight and extra fine weave, such as tailors' padding. The duty on this class, under the acts of 1897 and 1909, was seven-eighths of 1 cent per pound and 15 per cent ad valorem. An average of the actual and computed duties levied on this type, ranging between 28.01 and 21.75 per cent, amounted to 24.98 per cent in the period 1897–1913. The average price per pound was 8.51 cents.

The duty on the third class, which related to burlaps not specially provided for, was specifically set at 45 per cent. The average value of imports was 7.07 cents per pound in the years 1905–1913.

The duties collected on the first class of burlap, weighing not less than 6 ounces per square yard and not exceeding 30 threads to the square inch, which classification during the years 1897–1908 was further qualified by the provision "not greater than 60 inches in width," accounted for by far the greater part of the total. Of the whole revenue obtained, that imported under this heading contributed 85 per cent in 1900, 80 per cent in 1905, and 96 per cent in 1910.

Since 1914 imports of burlap have been divided into two classes: (1) Nonprocessed, and (2) processed. [40]

[40] The trade in processed burlap is discussed on pp. 69–74.

A number of firms have offered suggestions as to the amount and type of duty that might be placed on this commodity.

One of the companies which manufactured burlap during the years 1918 and 1919, writes:

* * * As regards the tariff, solely for revenue, a small duty might not be felt when equitably distributed over the great number of users of burlap, and a duty of even one-half cent per yard would probably bring in a revenue of between $3,000,000 and $4,000,000 per annum.

A prominent manufacturer of bags, writing December, 1920, states his opinion as follows:

* * * Assuming the necessity that this commodity should bear its share of the burden for purposes of revenue, we think that the duty should be a specific one of so much per pound, the rate being dependent largely upon the proportion it is decided that this commodity should necessarily bear. We suggest something between a half cent and 1 cent per pound on plain woven fabrics of single jute yarns, by whatever name known, not bleached, dyed, colored, stained, painted, printed, or rendered noninflammable by any process.

One of the largest importers of Dundee and Calcutta burlaps suggests:

We doubt if the trade in general care whether there is any duty or not placed on burlap so long as the duty is reasonable. A very high rate of duty would curtail the consumption in this country somewhat. The simplest form of duty would be a certain fraction of a cent per pound. This would require no record of market prices, etc., which is costly both to the importers and to the Government. In the last tariff, a duty assessed partly on weight and partly on value was used and worked satisfactorily on the whole. It is probably the fairest method.

If a tariff is placed on burlap, it is suggested that the duty on products which consist largely of burlap be increased proportionally.

One of the largest bag manufacturers west of the Rocky Mountains wrote, in December, 1920, as follows:

* * * On any duty that is levied on burlap there should be an additional duty on bags, equivalent to, say, 15 per cent or 1 cent per pound. In other words, if the duty on burlap should be fixed, say, at 15 per cent, then the duty on bags should be 15 per cent, and 15 per cent, or 15 per cent and 1 cent per pound.

TARIFF HISTORY.

TARIFF CLASSIFICATION.

The term "burlap" appeared first in the tariff act of 1824, when it was listed with sailduck, osnaburgs, and ticklenburgs as being dutiable at 15 per cent. The term "burlap" as used in that act is to be considered as designating a coarse cloth of linen or hemp, as the uses of jute previous to 1835 were unknown to all the world but India. It was not until 1846 that jute was mentioned in an American tariff act, when a duty of 25 per cent on raw jute and jute mats, was imposed.

The first reference to burlaps of jute appears in 1861, as follows: "On all brown or bleached linens, ducks, canvas paddings, cot bottoms, burlaps * * * or other manufactures of flax, jute or hemp * * * being of the value of 30 cents or under per square yard, 25 per centum ad valorem; valued above 30 cents per square yard, 30 per centum ad valorem." The duty on each class was increased ten per cent in 1864. Burlap had not then acquired the meaning which it now holds; i. e., plain woven cloth of single jute yarns.

The act of 1872 divided burlaps of flax, jute, and hemp into two classes: (1) burlaps, excepting such as might be suitable for bagging for cotton, dutiable at 30 per cent; (2) oilcloth foundations, or floor cloth canvas, dutiable at 40 per cent. These rates remained in the act of 1883, but a distinction was made by limiting fabrics of the first class to those not exceeding 60 inches in width, and of the second to those in excess of 60 inches.

The second class was eliminated in the act of 1890, which listed burlap not exceeding 60 inches in width, of flax, jute, or hemp, as dutiable at $1\frac{5}{8}$ cents per pound. Other burlaps fell under a general paragraph relating to all manufactures of jute or other vegetable fiber, not specially provided for, which if valued at 5 cents or less per pound, were dutiable at 2 cents per pound; and if valued above 5 cents per pound at 40 per cent ad valorem. As significant that the term "burlap" was becoming more and more limited to cloths made of jute is the paragraph in the act of 1890 levying a duty of 2 cents on "bags for grain made of burlaps."

The act of 1894 combined "burlaps and bags made of burlaps," and made them free of duty.

In contrast, the act of 1897 provided the most detailed classification of burlaps which had yet appeared. The term "burlaps" was no longer used; instead the expression "plain woven fabrics of single jute yarns, by whatever name known" was employed. Such fabrics on the basis of width, weight, and threads per square inch were specifically grouped into two classes: (1) Not exceeding 60 inches in width, weighing not less than 6 ounces per square yard and not exceeding 30 threads to the square inch, counting the warp and filling: (2) Those over 30 and not exceeding 55 threads to the square inch, counting the warp and filling. The duties were levied on a compound basis. The first class were assessed at five-eighths of 1 cent per pound and 15 per cent ad valorem, the second class at seven-eighths of 1 cent per pound and 15 per cent ad valorem. Imports not specifically mentioned, such as the extra-wide burlaps used for linoleum purposes, were dutiable at 45 per cent under the general paragraph relating to manufactures of flax, hemp, jute or vegetable fiber other than cotton.

This classification was reenacted in 1909 with two modifications: (1) An elimination of the words "not exceeding 60 inches in width," which caused imports of extra wide widths, used as the foundation for linoleum and floor cloths, to fall under the first clause of the specific paragraph; and (2) a reduction in the duty to $\frac{9}{16}$ of a cent and 15 per cent ad valorem on goods falling within the scope of the first part of the specific paragraph.

The act of 1913 adopted a new classification on the basis of whether the fabrics are unprocessed or processed. The former class, which describes burlap as taken from the loom, is admitted free; whereas imports of the second class are dutiable under paragraph 279, which levies a duty of 10 per cent on "plain woven fabrics of single jute yarns, by whatever name known, bleached, dyed, colored, stained, painted, printed, or rendered noninflammable by any process."

Court and Treasury Decisions.

Jute canvas with a *double warp and single filling*, each of single jute yarn, but which was *not twilled or figured* in any manner in the process of weaving, was held to be a plain woven fabric. (99 Fed., 262, of 1900.) Fabrics known as monks' cloth, woven with both a *double warp and a double weft*, from jute yarns not advanced beyond the condition of singles, were also held to be plain woven fabrics of single jute yarns. (G. A. 5269, T. D. 24191, of 1903.) *Merchandise designated as twilled burlaps of single jute yarns*, woven in such a manner as to present a twilled effect, are not plain woven fabrics of single jute yarns. The term "*plain woven*" means plain as distinguished from twilled or figured effects produced in the process of weaving. (G. A. 5035, T. D. 23386, of 1901, applying 99 Fed., 262, and G. A. 4785, T. D. 22560, of 1900.)

A plain-woven cloth, composed of jute yarns advanced beyond the condition of singles, *by grouping or twisting three or more single yarns together*, is not within the provision for fabrics of single jute yarns. (G. A. 5035, T. D. 23386, of 1901.) In G. A. 5269, T. D. 24191, of 1903, it is stated that the grouping spoken of in the last cited case does not refer to the grouping of the threads or yarns in the process of weaving, but to the assembling and twisting together of strands or small yarns in making coarser yarns, or yarns advanced beyond the condition of singles. In G. A. 5135, T. D. 23719, of 1902, it is indicated that a fabric of two or more single yarns grouped or twisted together would be removed from the provision.

The term "*printed*" as used in paragraph 408 of the act of 1913 applies only to such printing as affects the character or condition of the woven fabrics as such, whether by way of ornamentation or exploitation or like purpose. *The conspicuous stenciling* of the consignee's name upon a fabric for purposes of temporary identification does not make it a printed fabric. (Texas & Pacific Railway Co. *v.*

United States, 7 Ct. Cust. Appls., 328, of 1916, reversing G. A. 7888, T. D. 36342.

Plain woven jute fabrics cut up into pieces 26 inches in length, used for covering plants, with a selvedge on the sides, but the other edges rough and unfinished just as they were cut from the bolt, were held to be plain woven fabrics under paragraph 408 and not manufactures of vegetable fiber under paragraph 284 of the act of 1913. G. A. 8026, T. D. 37001, of 1917. *Merchandise returned as plain woven fabrics of single jute* yarns rendered noninflammable, found to be imported in bales and *shipped to a fireproof plant in the United States*, immediately upon delivery, where it was rendered noninflammable, and used in ventilating systems in coal mines, was held free of duty under this paragraph. The analyst reported that the material is inflammable. Abstract 39058, of 1916. *Jute thread waste*, the short broken warp ends of the jute thread used in the manufacture of burlap cloth, was held to be a thread waste and dutiable as a waste not specially provided for under paragraph 384 rather than free of duty under this paragraph. Waste, under this paragraph, must be a waste of bagging, gunny cloth, or similar woven fabric. United States v. Crumpton, 6 Ct. Cust. Appls., 197, of 1915. *Jute headings*, which are the ends cut off when a piece of woven jute fabric is taken from the loom and which consist of pieces of the fabric varying in width from one inch to a foot, to which are hanging the ends of the warp or yarn used in the weaving, are free under paragraph 408 as waste of plain woven fabrics of single jute yarn rather than dutiable under paragraph 384. G. A. 8581, T. D. 37113, of 1917. *Jute paid* of a plain woven fabric of cotton and jute, with jute in chief value, and used as interlining in coats, was held properly classified as a manufacture of vegetable fiber under paragraph 284 of the act of 1913 rather than exempt from duty under this paragraph as a plain woven fabric of single jute yarns. G. A. 8124, T. D. 37492; followed in Abstract 42975, which was affirmed: Simiansky v. United States, 5 Ct. Cust. Appls., 288, of 1914.

PART III.

PROCESSED BURLAP.

Description and Uses.

Paragraph 279 of the act of 1913 deals with plain woven fabrics, of single jute yarns which have been bleached, dyed, colored, stained, painted, printed, or rendered noninflammable.

Jute fabrics are processed for a wide variety of purposes; they are bleached and dyed for upholstery and for tapestry; they are colored for horse clothing and for packing hams; and are rendered noninflammable for use in mines.

All processed jute fabrics do not fall under the provisions of paragraph 279. Waterproofed fabrics with jute as chief value, such as tarpaulins, are dutiable under paragraph 254 at 25 per cent. Narrow woven jute fabrics, known as webbing and used in making belts, bands, etc., are assessed at 25 per cent under paragraph 202.[1]

Jute may be combined with cotton or flax to make actors' suits, tailors' padding, antique canvas, etc. Such cloths having jute as the constituent of chief value, processed or nonprocessed, pay a duty of 35 per cent under paragraph 284. Jute cloths woven with a twill, or made from plied yarns, either in the grey or treated states, are also included under paragraph 284.

Jute cloths used as wall coverings constitute the bulk of the fabrics falling under the description of "bleached, dyed, colored, stained, painted, printed;" brattice cloth is the main fabric under "rendered noninflammable by any process."

Brattice cloth, which is heavy coarse jute or cotton fabric treated with oils and mineral matter to preserve the cloth from decay and to render it noninflammable, is used for ventilation and for fire protection purposes in coal mines. The leading jute fabrics used in making brattice cloth are:[2]

Hessian, weighing 12 ounces to the square yard.
Hessian, weighing 16 ounces to the square yard.
Tarpaulin, weighing 16 ounces to the square yard.
Double warp bagging, weighing 20 ounces to the square yard.

The most satisfactory jute brattice cloth is made from fabrics specially woven, cropped, and mangled—run through heavy rollers to give the cloth a finished glazed appearance.

SUBSTITUTES FOR JUTE BRATTICE.

Cotton duck, ranging in weight from 8 to 12 ounces to the square yard is commonly used as the basis of cotton brattice cloth. The widths of the converted jute and cotton cloths range from 36 to 96 inches.

[1] Webbings are described on p. 36.
[2] These fabrics are described on pp. 33, 34.

Brattice cloth of jute is interchangeable with that made of cotton. A domestic manufacturer, whose production of cotton brattice in 1920 was twice as great as that of jute, writing in June, 1921, states: "The preference of the great majority of the mine operators is for cotton brattice, but the price is twice as high per square yard as that on jute, and the business is gradually drifting back to the jute brattice; although the cotton brattice, properly treated, has a longer life, and is preferred by the coal-mining interests, it is hardly possible to compete with the jute brattice on account of the great difference in price * * *."

Domestic Production.

The domestic production of jute brattice cloth made marked advances during the years 1914–1920. The output in 1920 was an increase of 70 per cent over that of 1918. The figures for 1914–1917 are not published because of the few firms then specializing in this line. In contrast, the amount of cotton duck converted in 1920 was 50 per cent less than in 1918.

Table 39.—*Domestic production of jute and cotton brattice cloth, 1918–1920.*

Year.	Jute.	Cotton.
	Square yards.	*Square yards.*
1918	1,982,500	1,825,936
1919	2,169,404	705,734
1920	3,380,826	832,364

On the basis of information furnished by a manufacturer, who converts both jute and cotton cloths, the value of the domestic production of jute brattice is estimated, in 1918 at $793,000, in 1919 at $759,000, and in 1920 at $899,000; and cotton brattice, $1,369,000, $458,000, and $370,000, respectively.

There were five plants in 1920 converting jute and cotton cloths for use in mines. Three of these were located in Chicago, and one each in Brooklyn and Pittsburgh. Three of these were specializing in jute brattice, and two in cotton. Only one was not making both types.

Drapery burlaps, classified in the census as upholstery materials, are not shown separately.

EXPORTS.

Official statistics divide exports into two classes, (1) domestic products or manufactures, and (2) commodities of foreign origin, changed from the form in which they were imported or enhanced in value by further manufacture in the United States. Articles of the second class are known as "Articles exported with the benefit of drawback," because upon exportation the importer of the foreign materials used in their manufacture is entitled to a refund of 99 per cent of the duties originally paid.

Statistics relating to our exports of processed jute cloths are limited to the second class. Such statistics, which are available under a number of different classifications, do not show the countries to which the goods are exported.

The amount of [illegible] consumed in the manufacture of articles so exported during the twelve months to [illegible] was based on the [illegible] was about [illegible] per cent of our total imports. In the interval [illegible] used in articles exported with drawback ranged between a minimum of [illegible] pounds in [illegible] and a maximum of [illegible] in [illegible]. The [illegible] such [illegible] was [illegible] in number in [illegible] and in the years [illegible] and [illegible] in [illegible]. The number of bags exported [illegible] in [illegible] in [illegible].

A classification was begun in [illegible] showing the [illegible] of various exports. In the following six years the number of bags shipped was a steady increase ranging between [illegible] bags in [illegible] and [illegible] bags in [illegible]. From [illegible] bags in [illegible] bags shipped in [illegible] the number [illegible] bags in [illegible] when this export classification was [illegible]. During the seven years [illegible] the amount of [illegible] imported in [illegible] and similar materials for grinding exported with drawback averaged [illegible] pounds to [illegible] pounds.

The position of the American exporter of [illegible] may be judged by the imports to Canada. A study of Canada's import trade shows that the American manufacturer [illegible] disadvantage as compared with the United Kingdom. The preferential tariff rate given to [illegible] goods is [illegible] greater percentage.

[illegible] normally supplies Canada with [illegible] of the [illegible] of the entire [illegible] Canadian market [illegible] [illegible] manufacturers [illegible] [illegible] per cent ad valorem and [illegible] per cent duty and Canada is entitled [illegible] per cent of the British [illegible] In the period [illegible] while [illegible] imports of this type of [illegible] [illegible] and [illegible] [illegible] [illegible] respectively. British [illegible] [illegible] [illegible] [illegible] per cent and [illegible] per cent in the second [illegible] per cent and [illegible] per cent. [illegible] the imports were [illegible] [illegible] [illegible] [illegible] per cent, the United Kingdom [illegible] per cent and the [illegible] per cent.

Canada's imports of [illegible] [illegible] [illegible] and [illegible] carpets, rugs, matting, and mats are negligible.

In [illegible] the exports of [illegible] manufactures to Canada, [illegible] specially enumerated, ranged in value between $[illegible] and $[illegible] as compared with $[illegible] and $[illegible] [illegible] [illegible] On this class of goods English manufacturers [illegible] [illegible] and the American 25 per cent.

Foreign Possessions.

Trade statistics of the United Kingdom and [illegible] which furnish all but a very small [illegible] [illegible] processed jute cloths do not appear separately [illegible] which have been dyed, stained, or printed [illegible]

IMPORTS.

Imports into the United States of plain-woven processed jute cloths are small compared with the domestic production of burlap received in the gray—as taken from the loom—and treated by domestic processes.

Imports for consumption under paragraph 279 averaged in the fiscal years 1914–1921 2,092,244 pounds, with a value of $258,637. Shipments were largest in the period October, 1913–June, 1914, when they were 3,768,108 pounds, valued at $345,697. Imports in the years 1915–1921, ranged between 1,140,362 pounds in 1918 and 2,193,896 pounds in 1919.[3] These figures relate only to imports of plain-woven fabrics of all jute. Shipments of processed twilled cloths, or of cloths composed in part of jute, which fall under paragraph 285, are not separately classified.

Brattice cloth constitutes the bulk of imports under paragraph 279. Noninflammable cloth made from twilled sacking is also entered and pays a duty of 35 per cent under paragraph 284. Burlap, which has been bleached or colored for buckram, or dyed red and used for horse blankets or clothing, is imported in negligible quantities.

As in the case of imported plain burlap and bags, the domestic consumption of foreign processed burlap is supplied by the United Kingdom and British East India, the former supplying two-thirds of the total quantity. In the periods 1915–1919[4] and 1919–20 shipments from the United Kingdom constituted 64.4 per cent and 66.9 per cent; and those from India 24.6 and 30.4 per cent, respectively. During the fiscal year ended June 30, 1921, the respective percentages were 72.90 for the United Kingdom and 25.07 for India.

Plain burlap from Dundee costs more than the processed article, whereas in India the article rendered noninflammable commands, as a rule, the higher price.

TABLE 40.—*Prices of imported burlap, plain and processed, 1915–1921.*[1]

[In cents per pound.]

Fiscal year.	Plain burlap.		Processed burlap.	
	United Kingdom.	British India.	United Kingdom.	British India.
1915	9.81	6.69	8.53	6.75
1916	13.19	8.37	10.61	8.74
1917	16.22	9.98	11.70	.....
1918	19.79	12.80	14.61	18.80
1919	21.01	17.33	21.18	11.78
1920	24.99	15.27	20.57	13.19
1921	21.69	11.17	15.85	13.62

[1] The prices of jute cloths rendered noninflammable (brattice cloth) in the United States are given on p. 67.

The higher price of the plain cloth from the United Kingdom is due to the fact that the nonprocessed burlap is superior in quality to that used as the foundation for brattice cloth. Jute paddings and linoleum burlap, which make up the bulk of the English hessian

[3] Imports of processed burlap, in the calendar year 1921, were 1,016,418 pounds, valued at $105,263.
[4] Imports of processed burlap by countries are first available for 1915.

consumed in the United States, sell for considerably more than the same weight of tarpaulin or double-warp bagging, which are the types of burlap commonly employed as the basis of brattice cloth.

COMPETITIVE CONDITIONS.

The American producer of jute brattice cloth, draperies, or other articles that have burlap as a basis, pays more for his labor than his British competitors. Wages paid in the United States, the United Kingdom, and in British India, are compared in the discussion of the domestic trade in nonprocessed burlap. In Dundee the converting processes are carried on by establishments which are independent of jute mills, and which make a specialty of bleaching, dyeing, and processing cloth.

[1] Production discontinued.

Processed burlap [1]*—Rates of duty.*

Act of—	Paragraph.	Tariff classification or description.	Rates of duty, specific and ad valorem.
1913	279	Plain woven fabrics of single jute yarns, by whatever name known, bleached, dyed, colored, stained, painted, printed, or rendered noninflammable by any process.	10 per cent ad valorem.

[1] Previous to the act of 1913, no distinction was made between burlap in the gray, and burlap which had been bleached, colored, etc.

COURT AND TREASURY DECISIONS.

Hop cloth, a plain woven fabric of single jute yarns, weighing not less than 6 ounces per square yard, and not exceeding 30 threads to the square inch, with a *2-inch colored stripe*, was held to be dutiable under the paragraph relating to burlap in the act of 1909. Paragraph 352 was also held to include similar cloth containing dyed, colored, or printed stripes (T. D. 32320, of 1912).

Brattice cloth, a jute fabric, treated with wood tar, oil, and mineral matter, was held dutiable as "plain woven fabrics of single jute yarns" under paragraph 352, act of 1909, and not as a manufacture of jute (G. A. 7104, T. D. 30967, of 1910). Jute fabrics, returned as plain woven fabrics of single jute yarns rendered noninflammable, found to be shipped upon delivery to a fireproofing plant and there rendered noninflammable, was held free of duty under paragraph 408 of the act of 1913. (Abstract 39058, of 1916.)

Plain woven jute burlap in the piece, 40 inches wide, *having a colored stripe 2½ inches wide* running lengthwise throughout the center of the fabric, the stripe being produced by colored warp threads, is dutiable as colored under paragraph 279 of the act of 1913, rather than free of duty under paragraph 408. (Abstract 42793, of 1918.)

Canvas cloth colored, consisting of a plain woven fabric of single jute yarns with a stripe running lengthwise about an inch from each edge, each stripe formed by four colored yarns, was classified as colored at 10 per cent ad valorem, under paragraph 279 act of 1913. It was found that the threads forming the stripes could not very well be removed without impairing the strength or integrity of the fabric. (Abstract 44508, of 1921.)

TABLE 48.—*Indian jute mills and their dividends, 1912–1921.*

PREFACE.

This is one of a series of Tariff Information Surveys prepared by the United States Tariff Commission and transmitted to the Committee on Ways and Means. The series covers all of the articles and commodities provided for in the tariff act of October 3, 1913, and others not specifically provided for. It is arranged in the numerical order of paragraphs of that act.

In some cases two or more paragraphs have been combined in one pamphlet. In doing this industrial relationship of the articles has been followed when possible. In those instances where a paragraph has been treated under a preceding paragraph of the tariff act reference is made to this fact at the point where the paragraph appears in numerical order. Where one grade of an article is dutiable and another grade of the same article is on the free list, the article is discussed under the dutiable paragraph, which appears first in numerical order in the tariff act. In certain instances articles of close industrial relationship and which occur in separate paragraphs of the tariff act have been combined under one paragraph for convenience of discussion. Reference is made to this fact at the point where the commodities would naturally occur in numerical order.

The first pamphlet in the series is an "Introduction and index," which contains:

1. An introductory chapter discussing the scope of the series and the general method of treatment.
2. An alphabetical index of the articles provided for in the tariff act of 1913, showing the paragraph of the act in which the article is provided for, and, if discussed under a different paragraph, the number of such paragraph.
3. A list of the pamphlets in the series, showing the paragraphs and articles included in each pamphlet.

Thus by use of this "Introduction and index" the exact location of the discussion relating to a given article or commodity can be ascertained.

In the preparation of this report the Tariff Commission had the services of John J. Cameron, of the textile division of the commission's staff, and of others.

NETS AND SEINES.

GILL NETTINGS, NETS, WEBS, AND SEINES OF FLAX, HEMP, OR RAMIE

TARIFF ACT OF OCTOBER 3, 1913.

PAR. 271. Gill nettings, nets, webs, and seines made of flax, hemp, or ramie, or a mixture of any of them, or of which any of them is the component material of chief value, 25 per centum ad valorem.

SUMMARY.

Flax is the chief material used in the production of gill nets, whereas seines are usually made of cotton. Hemp and ramie are seldom employed in the domestic manufacture of these articles.

The domestic consumption of fishing tackle made of flax is mainly supplied by American firms working on flax yarns spun in this country from imported flax. The domestic output is not known precisely, but the export trade is much larger than the import.

Record imports under paragraph 271, act of 1913, amounted to 66,664 pounds, valued at $64,320, in the fiscal year 1918. Imports in the fiscal year 1922 were 13,864 pounds, valued at $14,444. These were mainly gill netting from the United Kingdom.

Flax fish nets exported with the benefit of the drawback in 1920 amounted to 25,590 pounds. In the years 1905–1920 fish nets so exported totaled 401,814 pounds, as compared with imports under this paragraph of 395,896 pounds in the same period. Over half of Canada's total imports of textile fishing tackle originates in the United States.

Imports of cotton fishing nets are small, and are supplied mainly by the United Kingdom and Japan. The record export to this country from Japan amounted to 43,321 pounds in 1917, valued at $24,081.

GENERAL INFORMATION.

DESCRIPTION AND USES.

The word "gill" has been held to qualify nets as well as nettings.

The paragraph relates only to fishing appliances made of flax, hemp, or ramie, or a mixture of any of these materials. Those manufactured in whole or in chief value of cotton are dutiable as "manufactures of cotton." Since cotton is now much more extensively used than flax in the production of fishing nets, this survey includes a description of such articles when made of cotton.

Gill netting is the netting used in the construction of fish nets. It is made by crossing threads, twines, or cords, and knotting the intersections to form meshes.

The types of gill nettings are many, varying according to the kind of fish to be caught. For taking trout, herring, or smelt the single-knot linen gill netting commonly employed ranges in mesh from 1½ inches, by quarter of inches, up to 4 inches; it is usually 100 meshes

deep and made of twine size No. 20, 3-cord. In contrast, the double-knot linen gill netting commonly employed to take salmon is usually made from No. 40 thread, ranging from 4 to 15 ply.

The same diversity exists in cotton gill netting. That made of fine cotton, for catching trout, herring, or smelt, ranges by quarter of inches from 1½ to 3½ inches in width of meshes, is usually a hundred meshes deep and, when stretched, averages in length between 35 and 44 feet to the pound.

Gill nets are designed for catching fish by gilling; i. e., the mesh is of sufficient size to admit only the head, and thus slips under and back of the gills, to hold the fish.

In construction and length gill nets differ greatly, according to the locality where used and the kind of fish to be taken. Inland fisheries require a light thread and a small mesh, and the ocean fisheries a heavier twine and larger mesh. In size gill nets range from 50 feet when used in small inland streams to 1,600 and 1,800 feet when employed on the Great Lakes, where they are often set in strings from 8 to 10 miles long.

The leading types of gill nets are drift nets and set nets, made from either linen or cotton twine. The drift net is so rigged with a cork line, set on the surface of the water, that it floats in a perpendicular position with the tide. Set nets are attached to stakes or anchored. When used for taking surface school fish such nets are anchored on the surface; for taking ground fish they are set on the bottom. Drift and set nets differ. Trammel nets, for instance, a type of drift net constructed by hanging a web of small mesh netting of very light linen between two webs of coarse mesh, are usually made of 9-inch mesh outside and 2½-inch mesh inside. These nets are designed for use in rivers, creeks, and ponds. Among the leading types of set nets is the fyke net, a bag-shaped net which usually has its largest hoop between 4 and 5 feet in diameter. In length, this type of net ranges from 7½ to 9 feet. The size of twine commonly employed in its manufacture varies between No. 12 and No. 15 thread.

Gill nets of flax are mainly used in the fresh-water districts and less so in some of the salt-water sections, as in the salmon-producing districts of Alaska. An estimate places the number of salmon caught by means of gill nets made of linen twine as constituting 50 per cent of all the salmon packed.

Gill webs are pieces of netting that have not been hung or rigged to ropes. These webs are usually made from linen or cotton twine.

Seines are large nets having one edge provided with sinkers and the other with floats. Seines differ from gill nets in that they are designed for sweeping in the fish by bringing the ends of the seine together.

There are two classes of seines—purse, and haul or drag seines. Purse seines are employed for taking fish in the open sea and are operated by surrounding the school and bringing both ends of the seine together. Haul or drag seines are worked from the beach and dragged over the bottom. Seines used in American fisheries are manufactured from cotton. Those made from linen, hemp, or ramie are not used here.

According to the locality where used and the type of fish to be taken, the seines within these two classes differ greatly from one another. In size the salmon seine, as used on Puget Sound, averages in length about 275 fathoms (a fathom equals 6 feet), with a depth

of about 400 meshes of 3¾ inches No. 9 or 12 thread netting, with about 50 meshes of 5-inch No. 15 or 18 thread netting on the bottom of the seine. For taking salmon, the haul or drag seine commonly used averages in length about 150 fathoms, and in depth about 7 fathoms. The netting in the bunt—that is, the center or the bagging of the net—is usually of 3-inch mesh made from No. 15, 17, or 21 thread, and in the wings of 3½-inch mesh made from No. 12 to 15 thread. The same type of seine used for catching herring averages in length 100 fathoms and in depth 6 fathoms, with the netting used in the bunt of 1¼-inch mesh from No. 9 thread, and in the wings 1½ or 2 inch mesh made from No. 6 or 9 thread.

Pound nets, traps, and weirs are fixed apparatus, usually set in relatively shallow water near shore. The distinctive feature of such gear in its simplest form is a long leader of webbing (or brush), extending offshore, which deflects the fish through a V-shaped "heart" into a square or rectangular pocket or trap at the offshore end. The leader, which may be up to 900 feet or more in length, is of coarse-meshed netting (10 to 12 mesh, of 18 to 24 thread, are frequently used). The size of mesh and thread used on the sides and bottom of the trap varies with the size of fish and the fisheries for which used. In the salmon fisheries leader and sides of traps are frequently of wire netting.

This form of gear is extensively used in the coastal areas, along shore, in the bays and rivers, and in the interior waters; in point of value it exceeds that of any other form of fishing gear used in the fisheries of the United States.

Substitutes.—Cotton may be substituted in some cases for linen in making nettings and nets. For taking small or slow-moving varieties of fish, where strength of the net is not essential, nets made of fine cotton threads will suffice. Likewise, nets made of the coarse sizes of cotton twine can be employed in place of linen twine where the water is not so clear that the netting will be too plainly visible. Where a strong netting is required, as in the salmon fisheries, cotton is a poor substitute for flax.

DOMESTIC PRODUCTION.

Fifteen establishments in 1914 and 19 in 1919 manufactured fish nettings, nets, crab scrape bags, and seines of all materials. The capitalization of the 15 establishments in 1914 was $2,678,000 and of the 19 establishments in 1919, $4,156,000. The number of wage earners employed in this industry was 1,058 in 1914 and 859 in 1919, while the value of the output rose from $3,088,000 in 1914 to $5,114,000 in 1919.

Materials.—The fiber materials used in American fisheries are flax, cotton, and manila. Efforts were made in 1920 by the Japanese to introduce a netting made of ramie, and by the British to import quantities of netting made of hemp.

Flax, on account of its strength and durability, is extensively used in the construction of domestic nettings, nets, and webs. The leading domestic manufacturers of this class of fishing tackle spin their yarn. As the production of flax in this country forms but a very small percentage of consumption, and as practically none of the flax grown here is suitable for the manufacture of gill netting, nets, and

32705—23—J-2——2

webs, the domestic manufacturer is dependent upon imports for his raw materials. Because of the methods used in preparing domestic flax for spinning, the little flax produced is not suitable for gill nettings, nets, and webs, which require the strongest and best of flax.

Most of the flax imported for this purpose comes from Ireland, where it has been hackled to remove foreign materials and short and uneven fibers. Previous to 1914 hackled flax usually formed the lowest percentage of the different classes of flax imported. Imports of hackled flax during the years of 1910–1913 totaled about 1,500 tons, or 14 per cent. In 1914, upon the removal of the specific duty, of which the ad valorem equivalent had been about 11 per cent, imports of hackled flax rose to 2,590 tons and maintained this level during the next four years. Since 1918, however, imports of such flax have declined, amounting to 1,878 tons during the fiscal year 1922.

The domestic production of linen thread and twine is much larger than imports. In 1914 domestic concerns manufactured 5,707,668 pounds of linen thread, valued at $3,409,136, and 4,953,622 pounds of flax twine, worth $1,051,684. In the year ended June 30, 1914, imports of thread, twines, and cords of flax, hemp, or ramie, which were unusually large, totaled 784,936 pounds, valued at $442,674. In the calendar year 1919 the domestic production of linen thread amounted to 4,280,000 pounds, valued at $6,691,000, while imports of thread, twines, and cords of flax, hemp, or ramie amounted to 328,856 pounds, valued at $623,283.

Domestic manufacturers of fish nettings and nets, however, find it necessary to import a substantial part of their linen yarn, threads, and twine. A concern which sells the product of a number of netting mills, and of one net and netting mill, reports that these mills in 1914 imported about 21 per cent of all the linen yarn, thread, and twine employed in that year in the manufacture of fish nettings and nets and in 1919 about 20 per cent.

There are no figures available showing the quantities of flax consumed in the domestic manufacture of this class of fishing tackle.

A comparison of the raw materials used in nets of foreign make shows that the flax used is equal, if not superior, to that employed in nets of domestic manufacture. In workmanship there is little difference in nets made from fine linen and from fine cotton. Domestic nets of coarse linen and of coarse cotton, however, are superior to those made abroad in point of workmanship and, in nets of cotton, also in the grade of material used.

Cotton is the material usually employed in the manufacture of seines. In the manufacture of gill nettings and nets, cotton is freely substituted for flax. For instance, where the mesh in the gill net is not over 3 inches, thread made of long-staple cotton can be substituted for the finer sizes of linen thread.

The use of cotton in the fish netting and net industry has increased until in 1920 the quantities employed exceeded those of linen. In recent years, particularly during the war, owing to the scarcity of flax and to the relatively low price of cotton, there has been a marked substitution of cotton for linen. No figures are available to show the extent of this substitution.

Soft hemp is not used to any extent for fishing tackle. Under normal conditions the little hemp used is imported, as the hemp grown in the United States is not suitable.

Manila, the chief material for making domestic ropes and marine cordage, is used by the domestic fish-netting industry in the manufacture of trawls, which are bag-shaped nets. British competition restricts domestic production of trawls, which are becoming more and more important in the fishing industry. The domestic producer, however, faces no difficulties in securing his supplies of raw manila. During the fiscal years 1910–1918 imports of manila fiber for manufacture, which are duty free, ranged between a maximum of 93,308 tons and a minimum of 49,287. In the calendar years 1919–1921 imports for consumption averaged 55,835 tons, having been 31,503 tons in 1921. The duty on manufactures of manila was 35 per cent in the act of 1913 and is 40 per cent in the act of 1922.

Ramie has not been used in this country as a raw material in the manufacture of fish nettings, nets, webs, and seines. One domestic manufacturer attributes this to the fact that ramie is not well adapted to gilling purposes; that the fiber is too hard, though it feels soft. Early in 1920, however, the Japanese were endeavoring to introduce fishing appliances made of this fiber.

Domestic consumption.—Fishery apparatus employed in the fisheries of the United States and Alaska is valued at not less than $15,000,000. The greater part of this investment is in nets, netting, and lines of cotton, flax, hemp, etc. Much of this material must be replaced annually or at the end of the second year. The annual investment is believed to be not less than $5,000,000.

Pound nets, traps, and weirs represent 42 per cent of the total investment in fishery apparatus; gill nets, 28 per cent; seines, 12 per cent; lobster pots, 4 per cent; and lines, 3 per cent. Many other forms of fishing apparatus which make use of webbing are employed; these include fyke nets, stop nets, beam and other trawls.

The approximate number and value of various forms of fishing apparatus used in the United States are shown in the following table:

Fishing apparatus of the United States.

[Based on reports of the U. S. Bureau of Fisheries.]

Kind.	Number.	Value.
Pound nets, trap nets, and weirs	18,000	$6,350,000
Gill nets	224,000	4,200,000
Seines	5,540	1,877,000
Lobster pots	247,000	623,000
Trammel nets, fyke nets, and stop nets	.....	579,000
Beam and other trawls	.....	79,000
Lines	.....	515,000
All other	.....	777,000
Total	.....	15,000,000

Equipment.—Gill netting is manufactured almost exclusively by machinery. The greater number of the nets, however, are made by the fishermen themselves, the manufacturers supplying the web and perhaps the lines, floats, and leads, and the fishermen assembling them during idle or off-season periods.

Methods of production.—The manufacture of netting is complicated. The nets are made of practically any size thread and any size mesh; often the same nets contain a combination of various sizes of mesh.

Organization.—The same firms specialize in fishing articles made of linen and of cotton. The nature of the fishing industry is such that it is necessary for these firms to keep large and quickly available stocks of supplies to meet the sudden and irregular demands of the fisheries.

The greater part of the flax nettings and webs consumed in this country is sold through the agency of one company, which is the selling representative of a combination of the largest American and English mills producing linen threads, twines, nettings, and nets.

Geographical distribution.—The manufacture of nets and seines is practically confined to the eastern part of the United States. Of the 19 establishments manufacturing these articles in 1919, 68.42 per cent were located in Connecticut, Massachusetts, Pennsylvania, Illinois, and Maryland. Of the other six, only two were not in the Eastern States; one in Missouri and one in Washington.

Domestic production.—The combined production of a number of domestic firms engaged in the manufacture of linen nettings and nets was about 28,000 pounds greater in 1914 than in 1919.

In point of quantity, the combined production of nettings, nets, webs, and seines made from cotton is several times greater than that manufactured from flax.

In contrast to the production of fishing appliances made from linen, the production of such articles made of cotton was greater in 1919 than in 1914.

The quantity of gill nettings, nets, webs, and seines made in this country from hemp is negligible. Ramie is considered unsuitable for the manufacture of this class of fishing tackle.

EXPORTS.

Exports are not separately recorded in American export statistics.

The trade with Canada, however, which admits such articles free of duty, shows the strong position held by American manufacturers in the Canadian market, and indicates the strength of the leading foreign competitors.

Imports by Canada from the United States of fish lines, nets, trawls, seines, twines for fishing nets, without reference to the textiles used in their manufacture, and of manila rope not exceeding 1½ inches in circumference for use in fisheries, averaged annually about $600,000 for the years 1910–1914 and about $916,000 for the years 1915–1918. For the years 1919, 1920, and 1921 Canadian imports from the United States were valued at $1,469,788, $1,528,337, and $1,295,266, respectively, and constituted more than half the value of Canadian total imports of such articles for use in the fisheries. For the period 1910–1914 the United States furnished Canada with 52.37 per cent of all her imports; for the period 1915–1918, 56.62 per cent; and for the years 1920 and 1921, 63.60 per cent and 48.09 per cent, respectively. The United States shares Canada's import trade in fish nettings, nets, webs, and seines with the United Kingdom. Only in 4 of the last 20 years, viz, 1902, 1908, 1915, and 1921, have imports from the United Kingdom exceeded ours. From these two sources Canada receives all but 2 or 3 per cent of textile articles used in her fisheries. Japan is the only other country that has within recent years furnished more than 1 per cent. For

the periods 1910–1914 and 1915–1918 the percentages supplied by Japan were 1.56 and 0.087, respectively. For the years 1920 and 1921 the percentages were 1.15 and 1.02, respectively.

Fifty per cent of the fish nets exported into Canada, it is estimated, are for American fishing concerns operating there. In turn, a very large percentage of the fresh-water fish caught in Canadian waters comes here and constitutes a large part of the fish consumed in the Middle West.

According to the report of the domestic company which sells to the trade the larger part of the netting and nets consumed in this country, Canada, Norway, Denmark, and Sweden received the greater part of the goods exported in the years 1914 and 1919.

Domestic exports of gill nettings, nets, webs, and seines made of cotton are many times greater than those made of flax. Reports from a number of companies show that their combined shipments abroad in 1914 of cotton netting were six times, and in 1919 about seven times, greater than their shipments of linen netting. The same companies report considerable shipments of purse seines during the year 1919.

Export trade in recent years has not suffered to any great extent from the competition of substitutes or from the tariff operations of any country. The only handicap has been the world shortage of flax since the beginning of the World War.

Drawback.—The quantity of exports of linen fish nets, made from imported materials, designed for foreign consumption and exported with the benefit of drawback, is large and about equal to that of nettings, nets, webs, and seines of flax, hemp, or ramie imported for domestic consumption. During the years 1905–1919 the quantities of fish nets imported with the benefit of drawback were slightly greater. As compared with a total of about 376,000 pounds of fish nets made in this country from imported materials and exported during these years with the benefit of drawback, imports of nettings, nets, webs, and seines manufactured from flax, hemp, or ramie for domestic consumption, totaled about 365,000 pounds. By five-year periods, beginning 1905, shipments abroad of flax fish nets exported with the privilege of drawback were greatest during the middle period 1910–1914, when they were about two-thirds in excess of the quantities shipped during the five years immediately preceding or immediately following. Total exports for each five-year period were: 1905–1909, about 102,000 pounds; 1910–1914, about 170,000 pounds, and for 1915–1919, about 104,000 pounds. During the fiscal year 1920 the quantity so exported was 25,590 pounds, on which the drawback paid amounted to $10,050.

FOREIGN PRODUCTION.

The United Kingdom is among the world's foremost producers of fishing tackle. The average yearly value of her exports of fishing tackle, which classification includes hooks, nets, lines, and twines used for fishing purposes, without reference to the materials from which manufactured, were during the years 1915–1918, about 37 per cent greater in value than for the previous five years. As compared with a yearly value of $2,051,419 for the years 1910–1914, her exports for the next four years, 1915–1918, averaged yearly $2,829,436. In 1919 they amounted to $5,002,460, but in 1920 dropped to $1,064,323 in value.

Japan's total exports of fish nets to all countries, not including Korea, declined from 492,904 pounds in 1913 to 321,347 pounds in 1915. During the next three years they increased to 1,004,892 pounds in 1918. In 1919 they were 1,048,405 pounds, valued at $534,891, and in 1920, 768,741 pounds, valued at $632,576.

IMPORTS.

American import statistics are limited to those showing the quantity and value of gill nettings, nets, webs, and seines of flax, hemp; or ramie, entered for consumption; they make no mention of countries from which imported.

For the first three years of the World War, imports of this class of flax fishing tackle ranged between 21,000 and 30,000 pounds. With totals of 66,644 and 48,684 pounds for the fiscal years 1918 and 1919, respectively, imports were the greatest on record during the past 20 years. For the five fiscal years 1915–1919 imports of linen nettings, nets, webs, and seines averaged yearly 38,634 pounds, as compared with 9,827 pounds for the corresponding period, 1910–1914, and 24,500 pounds for 1905–1909. In the fiscal year 1920, 14,000 pounds were imported.

That imports were so large during the years 1918 and 1919, when flax was difficult to obtain, owing to the lack of transportation facilities and to the collapse of Russia as a grower of flax, is due to the fact that the United States Food Administration fostered the growth of the fish-netting industry during American participation in the war by assisting in obtaining its greatly increased requirements.

Though the tariff acts of 1913 and 1922 have added hemp and ramie to flax as the materials from which fish nettings, nets, webs, and seines might be made, the above figures remain comparable, imports of those made of hemp or ramie having been negligible.

The United Kingdom is the chief foreign source for domestic supplies of flax materials used in the fisheries. The value of her exports to this country of hooks, nets, and lines, given without reference to the materials from which constructed, show a marked decline during 1910–1913 and a corresponding increase during 1914–1918. They fell from $213,729 in 1910 to $110,221 in 1913. During 1914–1918 ranging between $193,205 and $272,534, they averaged yearly $227,450, while in 1919 and 1920 they amounted to $251,160 and $66,720, respectively.

What data there are available show that our imports of this class of fishing tackle consist chiefly of linen gill netting. The domestic firm which supplies the trade with the greater part of its fish nettings and nets states that previous to the war there was imported annually into Portland, Oregon, a very large quantity of salmon gill netting of flax from Great Britain.

Flax yarns not finer than 5 lea are the leading yarns used in the construction of imported fish nettings, nets, webs, and seines. For instance, the percentages of our total imports manufactured from yarns not finer than 5 lea were 76 in 1900, 88 in 1905, and 58 in 1910.[1]

Imports of cotton fishing nets from Japan have increased since 1915. In the years 1910–1914 our consumption of Japanese nets

[1] The sizes of the yarns used in the manufacture of imported flax gill nettings, nets, webs, and seines are not given after 1913.

was greatest in 1912, when it aggregated 4,973 pounds, valued at $1,587. During the next three years, shipments from Japan rose in quantity from 6,558 to 43,321 pounds, and in value from $3,787 to $24,081. From the peak reached in 1917, exports to the United States declined to 21,801 pounds in 1918 and to 19,467 pounds in 1919, valued at $14,940. In 1920 there was a further decline to 8,797 pounds, valued at $11,964.

TARIFF HISTORY

Gill nettings, nets, webs, and seines since 1883 have been subject to varying types and rates of duty. The paragraph in the act of 1883 read as follows: "Seines and seine and gilling twine, 25 per centum ad valorem." In the act of 1890 the articles were listed as flax gill netting, nets, webs, and seines, and, according to the number of the yarn, were subject to compound duties. When made of yarn of a number not higher than No. 20, 15 cents per pound and 35 per cent ad valorem, and when made of threads or twines, the yarns of which were finer than No. 20, at 20 cents per pound, and in addition thereto 45 per cent ad valorem. The act of 1894 eliminated all mention of sizes of yarn and changed the duty to an ad valorem rate of 40 per cent. The acts of 1897 and 1909 assessed the duty on the basis of the threads, twines, or cords of which the articles were made, plus the addition, in the act of 1897, of 25 per cent ad valorem and in the act of 1909 of 20 per cent ad valorem. The act of 1913 imposed a flat rate of 25 per cent ad valorem. In the act of 1922 the basis for assessing the duty was again made the thread, twine, or cord of which the article is made—the highest rate imposed on any of such thread, twine, or cord being applicable to the entire article—plus 10 per cent ad valorem.

COMPETITIVE CONDITIONS.

Foreign competition is practically limited to nettings, nets, and webs, made of flax. The competition in those made of cotton is not great enough to exert any marked influence on the domestic trade.

Such advantages as the English manufacturer, who is the leading foreign competitor in fishing tackle of flax, possesses are not due to superior workmanship or to lower costs of converting the threads and twines into nets. A prominent American manufacturer of linen thread says, "There is no difference in the efficiency of the help."[1] That the American producer labors under no handicaps in costs of making the nets from nettings is shown by the fact that the output of flax nets during 1905–1920 from imported materials, exported with the benefit of drawback, was greater than the total imports of gill nettings, nets, webs, and seines. What advantages the English manufacturer may have arise from his obtaining raw materials at home, whereas the American producer is dependent upon foreign sources for his flax; furthermore, the English producer can find the best of machinery in the United Kingdom, whereas the American is obliged to import all his spinning machinery. Such machinery was dutiable at 25 per cent under the act of 1913 and is dutiable at 35 per cent under the act of 1922.

[1] Bank, cod, pollock, and mackerel fish lines, and mackerel, herring, salmon, seal, seine, mullet, net and trawl twine in hanks or coils, barked or not, in variety of sizes and threads, including gilling threads in balls, and head ropes for fishing nets, manila rope not exceeding 1½ inches in circumference for holding traps in the lobster fishery; barked marline, fishing nets, and net morsels of cotton, hemp, or flax, and fishing nets or seines, when used exclusively for the fisheries, and not including lines or nets commonly used for sportsmen's purposes.

Rates of duty on gill netting, nets, webs, seines of flax, hemp, or ramie.

Act of—	Par.	Tariff classification or description.	Rate of duty.
1883	347	(Schedule J). Seines and seine and gilling twine	25 per cent ad valorem.
		(Schedule N). Webbing, composed of cotton, flax, or any other materials, not specially enumerated or provided for in this act.	35 per cent ad valorem.
1890	367	Flax gill netting, nets, webs, and seines:	
		When the thread or twine of which they are composed is made of yarn of a number not higher than 20.	15 cents per pound and 35 per cent ad valorem.
		When made of threads or twines, the yarn of which is finer than No. 20.	20 cents per pound and in addition thereto 45 per cent ad valorem.
	371	All manufactures of flax or hemp, or of which these substances, or either of them, is the component material of chief value, not specially provided for in this act * * *.	50 per cent ad valorem
	374	All manufactures of jute, or other vegetable fiber, except flax, hemp, or cotton, or of which jute, or other vegetable fiber, except flax, hemp, or cotton, is the component material of chief value, not especially provided for in this act:	
		Valued at 5 cents per pound or less	2 cents per pound.
		Valued above 5 cents per pound	40 per cent ad valorem.
1894	272	Flax gill netting, nets, webs, and seines	Do.
	277	All manufactures of flax, hemp, jute, or other vegetable fiber, except cotton, or of which these substances or either of them is the component material of chief value, not specially provided for in this act.	35 per cent ad valorem.
1897	332	Flax gill netting, nets, webs, and seines shall pay the same duty per pound as is imposed in this schedule upon the thread, twine, or cord of which they are made, and in addition thereto.	25 per cent ad valorem.
	330	Threads, twines, or cords, made from yarn not finer than 5 lea or number, composed of flax, hemp, or ramie, or of which these substances or either of them is the component material of chief value,	13 cents per pound.
		If made from yarn finer than 5 lea or number	¾ of 1 cent per pound additional for each lea or number, or part of a lea or number, in excess of 5.
1909	342	Flax gill netting, nets, webs, and seines shall pay the same duty per pound as is imposed in this schedule upon the thread, twine, or cord of which they are made, and in addition thereto.	20 per cent ad valorem.
	340	Threads, twines, or cords, made from yarn not finer than 5 lea or number, composed of flax, hemp, or ramie, or of which these substances or either of them is the component material of chief value.	10 cents per pound.
		If made from yarn finer than 5 lea or number	12 cents per pound and ¾ of 1 cent per pound additional for each lea or number, or part of a lea or number, in excess of 5.

Rates of duty on gill netting, nets, webs, and seines of flax, hemp, or ramie—Continued.

Act of—	Par.	Tariff classification or description.	Rate of duty.
1913	271	Gill nettings, nets, webs, and seines made of flax, hemp, or ramie, or a mixture of any of them, or of which any of them is the component material of chief value.	25 per cent ad valorem.
1922	1006	Gill nettings, nets, webs, and seines, and other nets for fishing, composed wholly or in chief value of flax, hemp, or ramie, and not specially provided for, shall pay the same duty per pound as the highest rate imposed in this act upon any of the thread, twine, or cord of which the mesh is made, and, in addition thereto.	10 per cent ad valorem.
	1004	Threads, twines, and cords, composed of two or more yarns of flax, hemp, or ramie, or a mixture of any of them, twisted together, the size of the single yarn of which is	
		Not finer than 11 lea:	
		In the gray	18½ cents per pound.
		Boiled	20½ cents per pound.
		Bleached, dyed, or otherwise treated	23½ cents per pound.
		Finer than 11 lea and not finer than 60 lea:	
		In the gray	18½ cents per pound and ¾ of 1 cent per pound additional for each lea or part of a lea in excess of 11.
		Boiled	20½ cents per pound and ¾ of 1 cent per pound additional for each lea or part of a lea in excess of 11.
		Bleached, dyed, or otherwise treated	23½ cents per pound and ¾ of 1 cent per pound additional for each lea in excess of 11.
		Finer than 60 lea:	
		In the gray	56 cents per pound.
		Boiled	58 cents per pound.
		Bleached, dyed, or otherwise treated	61 cents per pound.
		Provided, That the duty on the foregoing threads, twines, and cords shall not be less than	30 per cent ad valorem.
	1624	Nets or sections of nets for use in other trawl fishing, if composed wholly or in chief value of manila or vegetable fiber.	Free.

Court and Treasury Decisions.

Nets made of flax yarns of a number not higher than 20 and used in fishing for shrimps were held to be dutiable as nets and not as manufactures of flax or of jute or other vegetable fiber. (G. A. 2804, T. D. 15410, of 1894.)

Fishing nets composed of cotton were held not to be dutiable under the provision in paragraph 339 of the act of 1897 for "nets or nettings, * * * composed wholly or in chief value of * * * cotton," but under paragraph 322 as "manufactures of cotton." (Ederer *v.* United States, T. D. 25111, of 1902.)

Large fish nets or trawls for deep-sea fishing were excluded from paragraph 271 of the act of 1913 as nets made of hemp because the so-called "manila hemp" of which they were composed was shown not to be a true hemp in the tariff sense. They were held to come within paragraph 284 as manufactures of vegetable fiber, n. s. p. f. (G. A. 8316, T. D. 38252, of 1920.)

The word "nets" under the rule of ejusdem generis is limited to those used in fishing and fisheries, and the word "gill" before nettings also qualifies nets. Tennis nets made from Russian hemp are accordingly not within the provision, but fall within paragraph 284 as manufactures of hemp. (Abstract 36875, T. D. 34920, of 1914; G. A. 7745, T. D. 35562, of 1915.)

Cotton nets used to lift fish out of the water after having been hooked up, and specially excepted from paragraph 165 of the act of 1909, were held more specifically provided for as nets and nettings under paragraph 349 than as manufactures of cotton in paragraph 332 of that act. (Abstract 35739, T. D. 34496, of 1914.)

Cotton landing nets, minnow nets, etc., used by fishermen, are dutiable as "manufactures of cotton" under paragraph 266 of the act of 1913, and not as "nets or nettings" under paragraph 358 of that act. (G. A. 8109, T. D. 37410, of 1917.)

PREFACE.

This is one of a series of Tariff Information Surveys prepared by the United States Tariff Commission and transmitted to the Committee on Ways and Means. The series covers all of the articles and commodities provided for in the tariff act of October 3, 1913, and others not specifically provided for. It is arranged in the numerical order of paragraphs of that act.

In some cases two or more paragraphs have been combined in one pamphlet. In doing this, industrial relationship of the articles has been followed when possible. In those instances where a paragraph has been treated under a preceding paragraph of the tariff act reference is made to this fact at the point where the paragraph appears in numerical order. Where one grade of an article is dutiable and another grade of the same article is on the free list, the article is discussed under the dutiable paragraph, which appears first in numerical order in the tariff act. In certain instances articles of close industrial relationship and which occur in separate paragraphs of the tariff act have been combined under one paragraph for convenience of discussion. Reference is made to this fact at the point where the commodities would naturally occur in numerical order.

The first pamphlet in the series is an "Introduction and Index," which contains:

1. An introductory chapter discussing the scope of the series and the general method of treatment.
2. An alphabetical index of the articles provided for in the tariff act of 1913, showing the paragraph of the act in which the article is provided for, and if discussed under a different paragraph, the number of such paragraph.
3. A list of the pamphlets in the series, showing the paragraphs and articles included in each pamphlet.

Thus by use of this "Introduction and Index" the exact location of the discussion relating to a given article or commodity can be ascertained.

In the preparation of this report the Tariff Commission had the services of John J. Cameron, of the textile division of the commission's staff, and of others.

HOSE FOR CONDUCTING LIQUIDS OR GASES.

SUMMARY.

Hose used to conduct liquids or gases is mainly of cotton with a rubber lining; a smaller amount, made of flax, hemp, ramie, and jute, is used only in negligible quantities.

The United States is the largest producer and consumer of this type of hose. It is probably also the largest exporter. Prior to 1918 imports were negligible; since then they have increased. The increase has been largely due to the fact that the high price of flax yarns destroyed the differential provided in the act of 1913 between the ad valorem rate on the yarns from which the hose is made and the specific duty on the finished hose. Imports have been almost entirely of linen hose.

During the fiscal year 1922 hydraulic or flume hose imported for consumption totaled 81,609 pounds, valued at $112,668, or $1.38 per pound, as against exports[1] valued at $1,150,657, quantity not stated.

GENERAL INFORMATION.

TARIFF ACT OF OCTOBER 3, 1913.

Par. 274. Hydraulic or flume hose, made in whole or in part of cotton, hemp, ramie, or jute, 7 cents per pound.

DESCRIPTION AND USES.

Hose is a term employed to designate flexible tubing used for conveying fluids or air and other gases. Its important uses are for fire protection and as an item of equipment in every plant where water, steam, gas, oil, or other fluids are conveyed from point to point.

So varied are the uses of hose in industry that over 40 different types are produced, the most common being water,[2] fire, garden, pneumatic, air-brake, and air-drill hose. Although a number of different kinds of material are used in the manufacture of hose, that made of fabric and rubber in various combinations is the most extensively used.

"Hydraulic or flume hose," specifically mentioned in the tariff acts of 1909 and 1913, is the only type of fabric hose suitable for conducting water, all other types with the exception of flexible metal tubing being provided for under general or catch-all paragraphs. Other types are in chief value of leather; of leather with metal rivets and couplings; or of rubber not made in whole or in part of cotton, flax, hemp, ramie, or jute. The last class was dutiable under the general paragraph relating to manufactures of rubber.

[1] The classification covering these exports is "India-rubber, manufactures of—hose."

[2] "Water hose" is a restrictive term referring to a certain type of hose used to convey water. The term "water hose" does not include fire hose or unlined cotton and linen hose.

The common varieties of hose used to convey water may be grouped, according to the materials used in their construction, into three general classes:

1. Rubber hose.
2. Unlined linen hose.
3. Unlined cotton hose.

1. *Rubber hose* is constructed of a rubber tube surrounded by a fabric covering. The great variety of uses to which it may be put, added to the fact that it can stand harder wear than any other type, makes it the most popular medium for conducting water. Rubber hose is ordinarily made and sold in this country in lengths of 50 feet, the sizes being indicated by internal diameters, expressed in inches. It may range in size from ¼ inch to 12 inches, and in the number of plies from one to six, according to the use for which it is intended. The principal size, 2½ inches, is extensively used for fire-protection purposes.

The chief types of rubber hose are:

a. Cotton rubber-lined hose.—This type, consisting of a rubber tube surrounded by a tubular woven cotton jacket, is employed where high pressures are to be encountered and where light-weight hose is desired. The cotton jacket strengthens the hose and the rubber tube or lining prevents leakage.

Cotton rubber-lined hose, though largely used for fire-fighting purposes, is also made in smaller sizes for garden and other light uses. The size 2½ inches, internal diameter, is most commonly used for fire service; sizes below 1 inch are for garden purposes.

b. Wrapped duck.—This type is made by surrounding a rubber tube with windings or plies of fabric, which has previously been coated with as much rubber as the fabric would hold. The chief advantage of wrapped duck hose is that its diameter may be of any size.

c. Braided hose.—In this type of rubber hose the rubber tube is covered by plies of braided cotton threads. Its chief advantages are that it can be made in any length desired, limited only by the facilities of the factory; that its construction calls for a minimum of machinery; and that when in service, it suffers less from kinking than any other type of hose.

2. *Unlined linen hose.*—This kind of hose, usually made of flax line yarn and, under normal conditions only to a limited degree of flax tow yarn or of hemp yarn, is employed to convey water under pressure without excessive leakage. Flax line yarn is made from selected flax fibers, whereas flax tow yarn consists of the fibers that remain, together with some woody fiber or shives, after the better flax has been removed. Owing to the fact that unlined linen hose is not able to withstand frequent service, and is, therefore, not suitable where the fabric will be subject to chafing or to rough or sharp surfaces, and that it does not properly adhere to rubber, its chief use is for indoor emergency fire-protective purposes. The principal size constructed is 2½ inches, though the 1½-inch size, because of its comparative lightness and the ease with which it can be handled is gaining in popularity.

3. *Unlined cotton hose.* This type of hose, of which there is comparatively little made, is sometimes employed where considerable quantities of water are to be conducted under little pressure, as in mining and railroad work. As it leaks to a considerable degree, it

is rarely used for fire-protection purposes. In size this type of hose ranges from 3 to 12 inches.

DOMESTIC PRODUCTION.

In 1914 there were 11 establishments manufacturing rubber hose as their chief product and 7 others that reported it among their other products. In 1919, 7 establishments produced rubber hose as a chief product and 20 establishments reported it as a subsidiary product. The value of the rubber hose produced by the 27 establishments in 1919 was $26,998,292, as against $16,853,693 produced by the 18 establishments in 1914.

There were 5 establishments in 1914 and 4 in 1919 making woven hose. The 5 establishments in 1914 were capitalized at $339,000, employed 114 wage earners, and had a product valued at $477,000.[3] The 4 establishments in 1919 were capitalized at $4,258,000, employed 379 wage earners, and had a product valued at $3,344,000.

Materials.—Crude rubber, cotton yarn, flax line yarn, and, to a limited extent, flax tow yarn, are the chief raw materials entering into the production of hose manufactured to convey water. Hemp, ramie, and jute do not enter to any appreciable extent into the production of hose.

a. Rubber.—During the years 1913–1917 domestic consumption of crude rubber, which is admitted free of duty, increased from about 50,000 tons to 175,000 tons, or from 50 per cent to 70 per cent of the world's consumption. The British and Dutch East Indies supplied 63 per cent of the crude rubber imported into the United States in 1917 and 77 per cent of that imported in 1921.

b. Cotton yarn.—Because of its cheapness, great tensile strength, and its superior adhesion to rubber, cotton is the most popular fabric used in the making of rubber hose.

Sea-island cotton, because of its strength, is the preferred material for hose, but aside from its relatively high price it is not available because of limited production. Long-staple American cottons are used in large quantities, together with an appreciable amount of imported Egyptian. All of the cotton yarn employed is spun in the United States. No. 12 cotton yarn is the chief size used in the production of rubber hose.

c. Flax yarn.—Because linen does not adhere closely to rubber, its use is chiefly restricted to unlined hose. The flax yarns used for hose purposes range in the main from 15 to 20 lea. These are mostly imported. During the war emergency, however, linen yarns as coarse as 10 lea were employed. Yarn made of domestic flax is not used for hose-making; the supply is small and it is said that the domestic method of retting the flax makes a fiber inferior to that made in Europe.[4]

[3] This does not include the woven hose produced by establishments engaged primarily in the manufacture of rubber and leather belting and hose or in the manufacture of awnings, tents, and sails.

[4] Retting (rotting) the vegetable gum which holds the fiber and the woody material together is carried on in Europe by soaking the flax straw in water in rivers or in stagnant pools, or else by scattering it on the ground and leaving it to the action of dew and sun. Only to a very limited extent is chemical retting employed—a process of subjecting the flax straw to chemicals, which shortens the time of fermentation and eliminates a great deal of hard labor. In the United States chemical retting is essential to overcome labor difficulties, but this process has not as yet been perfected and the fiber produced is considered inferior to that obtained by natural methods, usually being harsher and weaker.

The flax from which the yarn is produced has in the past been chiefly of Russian production. Prior to 1914 Russia produced about 85 per cent of the flax fiber of the world, and was the only country in which the production of flax fiber was increasing substantially. Nearly all of the flax yarn imported comes from the United Kingdom, chiefly from Belfast, Ireland, and Dundee, Scotland.

The yarn is for the most part imported in the single, and is subsequently doubled and twisted into threads of the required size and strength, the yarn as used ranging from 2 to 16 ply. It has been imported in the single mainly to avoid paying the higher duty on "threads, twines, or cords of flax."

Flax yarns for hose making are first freed of vegetable gums by being boiled in an alkaline solution.[5]

Previous to 1917 flax tow yarn was not extensively used as a substitute for line yarn in the production of linen hose. Of the total production in 1918, however, about two-thirds was made of flax tow and hemp yarn, principally of the former. In 1919 about half was flax line and half flax tow and hemp.

Although both flax line yarn and tow yarn make good hose, that produced from line is the more durable. Hose made of flax line has also greater durability than that produced from hemp line.

d. Hemp yarn.—As hemp does not combine well with rubber, because of its lack of elasticity, its use is confined to unlined hose. Under normal conditions very little hemp yarn is used in unlined hose. The British embargo on flax yarns in 1917 and 1918 caused the American manufacturers of hose to resort to the use of domestic hemp yarn as a substitute.

The American manufacturer, aside from being dependent on Europe for linen yarn, labors under no disadvantage in procuring supplies of raw materials adequate for his needs. During the years 1913–1921 the price of crude rubber fell because production continually kept ahead of consumption.

In the matter of obtaining cotton yarn for rubber hose and unlined cotton hose, the American producer has an advantage in that 99 per cent of the cotton yarn consumed in this country is of domestic production.

Domestic manufacturers of unlined linen hose have always been dependent, however, on Great Britain for their supply of linen yarn. This was recently shown by the curtailment of their production following the establishment of the British embargo on flax yarns in 1917 and 1918. The production of fiber flax in this country previous to 1914 showed a steady decline. In the period 1910–1913 annual imports averaged 10,939 tons, or over 95 per cent of the total consumption of the United States. Though under the influence of the war the acreage devoted to the raising of domestic flax fiber increased from 1,000 to 4,200 acres, the American manufacturer of hose preferred to use imported flax tow and domestic hemp yarn to the yarn produced from domestic flax. The chief handicap to the more extensive production of flax in this country, under normal conditions, has been the fact that it can not compete with our standard agricultural crops, which permit of a greater use of machinery and which demand a far less amount of trained yet tedious hand labor. The

[5] Underwriters' Laboratories specifications for unlined linen hose.

market on all flax products has been in a very precarious condition since 1914, because of Russia's participation in the war and the ensuing internal disorder. Until her political and industrial conditions again become normal the world can not count on Russian flax. The problem, therefore, is not so much to obtain flax from Russia as to extend sowings elsewhere. The lack of flaxseed further complicates the situation.[6]

Equipment.—The manufacture of rubber goods originated in the United States, and American manufacturers have always been foremost in the perfection and use of mechanical devices employed in the manufacture of articles made of rubber. The process of manufacturing rubber hose calls for a great variety of mechanical devices and attachments. In 1919 electric power formed 45 per cent of the total primary power for the rubber industry, as compared with 17 per cent in 1914 and .6.5 per cent in 1909. Steam power constituted 53 per cent of the primary power employed in 1919.

The American manufacturer of woven hose is not dependent on foreign sources for machinery used for twisting his yarns, or for weaving the twisted yarn into hose.[7]

Methods of production.—The general types of construction employed in manufacturing hose used to convey water may be grouped, according to the character of the hose, into two classes: (1) Rubber hose, (2) unlined hose.

1. *Rubber hose.*—Various methods are employed in making rubber hose out of rubber tubing. The manufacture of rubber tubing out of rubber stock is done both by hand and by machine.

Hand-made tubes.—The stock for hand-made tubes is composed of sheet rubber built up layer upon layer. This method prevents defects, one fold covering up any imperfections that may occur in another. These sheets are then shaped around mandrels—i. e., smoothly finished iron rods or steel pipe, usually 50 feet long—their edges being brought together on the mandrel in a lapped seam. The seam is then vulcanized—that is, subjected to the action of sulphur and heat—a process that adds to the strength and elasticity of the tube.

Machine-made tubes.—Machine-made tubes are constructed on standard machines known as tubing or spewing machines. The stock for machine-made tubes is supplied in thick slabs of rubber, which are cut into strips and then fed into the hopper of a tubing machine, being forced into the form of a tube through a slightly heated die by means of a spiral worm.

From the completion of the rubber tubing, rubber hose is made by one of three principal methods: (*a*) Rubber-lined cotton, (*b*) wrapped duck, (*c*) braided.

a. Rubber-lined cotton hose.—Though rubber-lined cotton hose is largely employed for fighting fire, the smaller sizes are also made in limited quantity for garden use. This type, known also as woven hose, consists of a rubber tube surrounded by a tubular woven cotton jacket. The jackets are woven for the most part on seamless looms. Any length of jacket may be woven,

[6] Linen Trade Circular, Belfast, Jan. 17, 1920.
[7] Tariff Hearings before Committee on Ways and Means, 1909, p. 4750.

but 50 feet is the usual length. In making hose for fire-fighting purposes one jacket is usually pulled into another to form what is popularly termed double cotton-jacketed rubber-lined fire hose. In sizes above ¾ inch inside diameter the tube and jacket are constructed independently, the tube or rubber lining, which has been coated with an adhesive rubber backing, being pulled into the jacket and then vulcanized.

b. Wrapped duck.—In making this type of hose, the hose fabric is put through a process whereby it receives a rubber coating on each side. This rubber-coated fabric is then cut on a bias and the pieces spliced together into lengths of about 50 feet and of a width sufficient to form the number of wrappings desired in each case. The rubberized fabric and the cotton sheeting for the covers, if such are to be provided, are applied in one operation by revolving the rubber tube on mandrels between two iron rollers; simultaneously the fabric folds and the covers are fed on and wind themselves automatically around the tube. These are smoothed down and rolled tightly by means of a third roller brought to bear upon the mandrels. Long strips of wet muslin are then wrapped tightly over the hose to hold the various parts in their places until the process of vulcanization has been completed.

c. Braided rubber hose.—The rubber tube for braided hose is produced on a tubing machine in pieces of 250 to 500 feet long. Upon removal from the mandrel a slight air pressure is maintained within the tube in order to keep the walls extended to their normal size and shape. The tube is then fed vertically into the braiding machine from beneath, the spool carriers passing in and out around each other, so feeding the yarn as to cover the tube with the braided fabric. There are either 24, 36, or 48 of these spools according to the size of the hose desired. Upon completion of the first braided ply, the tube and single fabric coating are passed through the tubing machine, where they receive a covering of rubber compound. This now partially constructed hose is again taken to the braiding machine, where the second jacket of cotton fiber is supplied. This procedure is repeated until the required number of plies has been obtained. The rubber hose is then run through a tub and given a bath of soapstone to prevent the hose sticking to the mold when being vulcanized. At the same time the hose is passed beneath spike pulleys to puncture the cover slightly, and so destroy any air pockets, which would result in blisters forming on the cover during the vulcanizing process.

Combinations of the above types of construction are becoming more and more common, as it is found that for certain kinds of work the combination type possesses greater strength and flexibility.

Where a hose is to receive rough usage, a rubber cover is often placed around the fabric, in order that the fabric may not come into contact with agencies that will shorten its life. Rubber covers are applied in sheet form by being wrapped around the hose, or in tubular form by being built over the fabric. They are usually one thirty-second of an inch in thickness. Other means of protecting hose are by winding wire or rope on the outside and by embedding wire or cable in the walls.

2. *Unlined hose* is usually woven on seamless looms. Underwriters' specifications for unlined linen hose call for a seamless fabric of

firm and even texture. The amount of leakage depends on the closeness of the weave. In the case of unlined linen hose the cells swell when wet, causing the fabric to tighten; whereas in the case of the cotton fiber, the weaving can not be made close enough to prevent excessive leakage under pressure.

Organization.—Both the rubber and woven hose industries are fast losing their independence as separate industries. This is due, in the case of the rubber-hose industry, to the increasing concentration of the manufacture of all rubber articles into the hands of large rubber companies, which produce thousands of different articles; in the case of the woven-hose industry it is due to the increasing number of textile and rubber factories that manufacture woven hose in addition to their other products.

The tendency of the rubber industry to become concentrated in large establishments is shown by the fact that firms with products over $1,000,000 reported 94 per cent of the total value of products in 1919 and 80.8 per cent in 1909. A very large part of the rubber hose made in this country is the product of four firms, which specialize in the manufacture of rubber articles of every description and include practically every type of hose. The crude rubber consumed by these firms in 1917 was over three-quarters of that used by all the companies manufacturing rubber hose of every type. In 1914 the number of establishments making rubber hose as their chief product was 11, as against 7 in 1919.

The American manufacturer of rubber hose has, in the undisputed possession of his home market, the largest market in the world. As the American product is generally cheaper and of a better quality than that made abroad, the matter of imports and exports has little interest for the American producer compared with that of supplying the domestic demand, which is steadily growing as the uses of rubber hose in industry are increasing.

There is a tendency, likewise, for the woven-hose industry to be concentrated in the hands of a few old establishments. In 1914 there were five concerns making woven hose. Since 1914 one of the largest has been absorbed by a company that specializes in the manufacture of rubber goods of all descriptions.

The American producer of linen hose until 1918 had complete possession of his home market, and was able to compete more and more in foreign market. Only since 1918 has there been a show of foreign competition, and this has been due to special circumstances resulting from the high price of flax yarns.

Geographical distribution.—The rubber belting and hose industry centers in New Jersey, Ohio, and Massachusetts. In 1919 the value of such products in these States was $19,176,384 in New Jersey, $14,046,539 in Ohio, and $5,760,923 in Massachusetts.

History of the industry.—The first fire hose used in this country was of rawhide or leather. The most common varieties produced were made by building strips of leather over a form and then sewing the edges together.

The first rubber hose manufactured in this country was in 1839. This consisted of a long tube of rubber placed in a rubber-treated fabric jacket, which was sometimes overlaid with a cotton cover. The jacket was formed by strips of cotton cloth, the width of which

was proportionate to the circumference of the hose desired. These strips were covered with rubber and then wound one at a time around the tube, previously placed on a mandrel.

This method of manufacture was abandoned in 1877, when a means of weaving the seamless tube of cotton was discovered, so that to-day the woven hose has practically eliminated the use of that constructed of leather.

The braiding method, whereby cotton covers are applied, by means of a machine around the tube of rubber compound, after the manner that ribbons are braided on a May pole, came into general use about 1908.

Domestic production and consumption.—The domestic production of all types of hose used for conveying water has been more than sufficient to supply domestic consumption. Imports have always been negligible, being far less than exports. In 1919 production of rubber hose of all types was valued at $26,998,292. Two companies manufacturing unlined hose reported their production in 1914 as approximately 2,340,000 feet, and in 1919 as 1,520,000 feet. For the year 1914 imports were valued at $2,644. As compared with total imports of 4,979 pounds in 1914, two American firms manufacturing hose made of linen report shipments abroad for that year totaling 102,175 feet.

Trade size (inches).	Weight.
	Pounds per 100 feet.
1½	11½
1¾	14
2	18½
2½	23

Domestic exports.—Rubber hose was not separately listed in the official export statistics prior to 1920, being included in "india-rubber belting, hose, and packing." The exports of this group of rubber products has, with the exception of the years 1914 and 1915, shown an increase from 1910 to 1920, amounting to a total of $1,960,825 in the fiscal year 1910 and $8,398,401 in the calendar year 1920. During the calendar year 1920 exports of rubber hose were valued at $3,340,882, while in the calendar year 1921 their value was $1,945,300. Although they go all over the world, in 1921 Mexico, England, British South Africa, and Cuba combined took 58 per cent of the total.

IMPORTS.

Prior to the war imports of hydraulic or flume hose were negligible; in succeeding years they have been on a new level, however. These imports have been almost entirely unlined linen hose, the importation of which became profitable when the high prices charged for flax yarn destroyed the differential provided in the act of 1913 between the ad valorem rates on such yarns and the specific rate on hose made from them. In the fiscal year 1921 imports of hydraulic or flume

hose were valued at $171,932 and in 1922 at $112,668. In the fiscal year 1922 the ad valorem equivalent of the specific rate provided for hose in the act of 1913 is 5.07 per cent, as against an ad valorem rate of 20 per cent provided for the yarns from which such hose is made.

COMPETITIVE CONDITIONS.

In the invention and use of machinery for making rubber products the United States has always been foremost. It is also the largest producer of coarse cotton yarns such as are used in the manufacture of hose for conveying water.

In the case of flax yarns only is the American hose manufacturer dependent on Europe. This is due to the lack of development of flax growing and spinning in this country. Under normal conditions there has been no difficulty in purchasing flax yarns from abroad, but during the war, owing to the collapse of Russia and to the British embargo on the export of flax yarns, domestic manufacturers of flax hose were somewhat handicapped. Russia, before the war, produced about 85 per cent of the world's fiber flax. As long as its product is absent from the world's markets, flax yarns will doubtless continue high and scarce.

TARIFF HISTORY.

The first tariff mention of hydraulic hose was in the act of 1890 (par. 368), when a specific duty of 20 cents per pound was assessed on "linen hydraulic hose, made in whole or in part of flax, hemp, or jute." In the act of 1894 the rate was changed to 40 per cent ad valorem. In the act of 1897 the 20 cents per pound rate was restored, but the wording changed by the omission of "linen" before "hydraulic," and by the addition of "ramie" to the list of materials of which the hose might be made.

In these three acts woven cotton hose, which constitutes the great bulk of the hydraulic hose made, was not included, but was dutiable as countable cotton cloth.

In the act of 1909 cotton was added to the list of materials of which the hose could be made and the wording changed to "hydraulic or flume hose, made in whole or in part of cotton, flax, hemp, ramie, or jute." Hydraulic hose implies hose subject to hydraulic pressure, and the term "flume hose" was added, when cotton was included among the materials, probably to cover hose not intended to be subjected to hydraulic pressure, since some cotton flume hose is used in mining to carry off water or water and gravel. The 1909 wording was retained in the act of 1913, but the rate of duty changed from 15 cents per pound to 7 cents per pound.

In the act of 1922 the wording of the paragraph was changed to: "hose, suitable for conducting liquids or gases, composed wholly or in chief value of vegetable fiber, 17 cents per pound and 10 per centum ad valorem."

TARIFF CONSIDERATIONS.

The great bulk of the hose made in the United States for use in conveying water or other liquids or gases is made of cotton and rubber. There is no competition from abroad in such hose.

A small section of the American hose industry is devoted to the manufacture of linen hose, usually unlined, and imports are mainly of this type for use as indoor fire protection.

In the act of 1913 flax yarns suitable for hose manufacture were dutiable on an ad valorem base, at 20 per cent, whereas linen hose was dutiable on a specific base, at 7 cents per pound. A pound of hose requires more than a pound of yarn, owing to a waste of about 2 per cent of the weight of the yarn in the processes of doubling and weaving. It is estimated that 1 pound of yarn is required for the manufacture of 4 feet of unlined linen hose of 2½ inches internal diameter. During recent years prices of flax yarns have been so high that the ad valorem duty of 20 per cent resulted in the equivalent specific rates, in terms of cents per pound, being higher than the 7 cents per pound assessed on the finished hose.

The Linen Association of New York, in a brief submitted to the Committee on Ways and Means in 1913, suggested that the duty on irrigating or flume hose should be on an ad valorem basis and assessed at 25 per cent ad valorem. Imports were negligible at that time, but with the increase of imports after 1917 linen hose manufacturers urged that the duty on their raw material (flax yarns) and on the hose made therefrom should be on the same basis, whether specific or ad valorem, and so adjusted that the finished product would always pay the higher rate.

In the act of 1922 there is levied on hose suitable for conveying liquids or gases a compound duty of 17 cents a pound and 10 per cent ad valorem. Such imported hose is mainly of flax and the specific portion of the above duty is intended as compensation to the domestic hose manufacturer for the duty he has to pay on his yarns, which are mainly of the 15 to 20 lea sizes. The duty on flax yarns is specific and arranged on a progressive scale; on 15 lea boiled flax yarn it is 13½ cents a pound and on 20 lea it is 16 cents a pound. The compensatory duty is higher than that on the yarn in order to allow for the waste in yarn during the process of manufacture into hose.

STATISTICAL TABLES.

TABLE 1.—*Belting and hose—Production in United States.*

[From Federal Census.]

Year.	Rubber belting and hose.	Woven belting and hose.	Total.
1909	$8,169,000	$717,000	$5,886,000
1914	14,954,000	2,837,000	17,791,000
1919	19,288,000	5,491,000	24,729,000
1921	23,561,000	4,441,000	28,002,000
1923	34,211,000	19,176,000	53,387,000

1909	345	Hydraulic or flume hose, made in whole or in part of cotton, flax, hemp, ramie, or jute.	15 cents per pound.
1913	274	....do	7 cents per pound.
1922	1007	Hose, suitable for conducting liquids or gases, composed wholly or in chief value of vegetable fiber.	17 cents per pound and 10 per cent ad valorem.

COURT AND TREASURY DECISIONS.

In G. A. 6032, T. D. 26351, of 1905, it was pointed out that paragraph 335 of the act of 1897 did not provide for hydraulic hose made of cotton, and such hose was held dutiable as countable cotton cloth.

Canvas hose, not commercially known as "hydraulic hose," was held by the Treasury Department to be dutiable as a manufacture

of flax or other vegetable fiber, n. s. p. f., under paragraph 284 of the act of 1913, and not as "hydraulic hose" under paragraph 274 (Dept. Order, T. D. 34373, of 1914). In the next year the Board of General Appraisers held that seamless flax fire hose used for the conveyance of water under pressure was "hydraulic hose" within common understanding and dutiable as such under paragrah 274, and not as a manufacture of flax under paragraph 284 of that act. (G. A. 7809, T. D. 35879, of 1915.) This decision, however, was not acquiesced in by the Treasury Department (Dept. Order, T. D. 36036, of 1916), and in a later case (G. A. 8015, T. D. 36930, of 1917) the Government contended that the term "hydraulic hose" is confined in trade and commerce to a cotton hose not under 3 inches in diameter, which is used in connection with mining operations to convey water in mines and which will not hold water under working pressure. The Government furthermore contended that the hose in question was not commercially known as "hydraulic hose." Witnesses for the Government testified that they had not heard the term "hydraulic" connected with hose of this character. Some witnesses further testified that they had not heard the term "hydraulic hose" used in the trade at all, and none of them had ever seen any flume hose. The importers' witnesses testified to the contrary. Most of the witnesses agreed that the word "hydraulic" is ordinarily used in connection with anything that will withstand artificial water pressure. The Board of General Appraisers followed its former decision (T. D. 35879, *supra*) and said:

"The Government attempted to prove that the term 'hydraulic hose' is limited in trade nomenclature to a certain 'hydraulic mining hose' made of cotton and used for conveying water and minerals by gravity in mining operations, but we think the testimony falls far short of proving that there is any such general trade understanding. But even if it were proven it would be of no avail in this case, for the witnesses testified that this so-called hydraulic mining hose is composed entirely of cotton, or of cotton and rubber, and is never made of flax, hemp, ramie, or jute. Paragraph 274 provides for 'hydraulic or flume hose, made in whole or in part of cotton, flax, hemp, ramie, or jute.' The provision is not confined to cotton hose alone, and therefore Congress could not have had this hydraulic mining hose in mind when the law was enacted."

PREFACE.

This is one of a series of Tariff Information Surveys prepared by the United States Tariff Commission and transmitted to the Committee on Ways and Means. The series covers all of the articles and commodities provided for in the tariff act of October 3, 1913, and others not specifically provided for. It is arranged in the numerical order of paragraphs of that act.

In some cases two or more paragraphs have been combined in one pamphlet. In doing this, industrial relationship of the articles has been followed when possible. In those instances where a paragraph has been treated under a preceding paragraph of the tariff act, reference is made to this fact at the point where the paragraph appears in numerical order. Where one grade of an article is dutiable and another grade of the same article is on the free list, the article is discussed under the dutiable paragraph, which appears first in numerical order in the tariff act. In certain instances articles of close industrial relationship and which occur in separate paragraphs of the tariff act have been combined under one paragraph for convenience of discussion. Reference is made to this fact at the point where the commodities would naturally occur in numerical order.

The first pamphlet in the series is an "Introduction and index," which contains:

1. An introductory chapter discussing the scope of the series and the general method of treatment.
2. An alphabetical index of the articles provided for in the tariff act of 1913, showing the paragraph of the act in which the article is provided for and, if discussed under a different paragraph, the number of such paragraph.
3. A list of the pamphlets in the series, showing the paragraphs and articles included in each pamphlet.

Thus by use of this "Introduction and Index," the exact location of the discussion relating to a given article or commodity can be ascertained.

In the preparation of this report the Tariff Commission had the services of W. S. Lewis of the Textile Division of the commission's staff, and of others.

HOUSEHOLD ARTICLES OF COTTON.

SUMMARY.

Act of 1913, paragraph 264. Towels, bath mats, quilts, blankets, polishing cloths, mop cloths, wash rags or cloths, sheets, pillowcases, and batting, any of the foregoing made of cotton, or of which cotton is the component material of chief value, not embroidered nor in part of lace, and not otherwise provided for, 25 per centum ad valorem.

Description and uses.—The items in paragraph 264 are chiefly, though not exclusively, articles of household use; cotton batting, for instance, is consumed in quantities by other industries, and polishing cloths find their greatest use in the automobile accessory business. With the exception of cotton batting, which is not woven, the articles enumerated are advanced but one stage beyond the manufacture of cloth and for the most part are finished in the mills.

Domestic production.—In 1919 the domestic production of all goods enumerated in this paragraph was valued at the mills at close to $100,000,000. These commodities do not represent distinct industries, as few establishments, usually only the smaller ones, make any of them exclusively. Possibilities of standardization and the large and continuous demand for these articles tend to insure the domestic market for American manufacturers.

Tariff reclassification.—The articles in paragraph 264 of the act of 1913 were not specially provided for in any previous tariff law. They were included in the "basket clause" covering unenumerated manufactures of cotton, which in the act of 1909 made them dutiable at 45 per cent. The rate under the act of 1913 is 25 per cent. On May 28, 1921, the emergency tariff act imposed an additional duty of 7 cents per pound upon raw cotton, the staple of which is 1⅜ inches or more in length, and upon manufactures of which such cotton is the component material of chief value.

Imports.—No definite import statistics are available prior to 1914, but it has been learned from the trade that polishing cloths, a rather insignificant item, were practically all imported prior to the war, since when the manufacture has been undertaken in the United States, and that imported quilts represent a class of goods expensive to produce in this country because of the fine materials of which they are made and the ornate designs which add to their cost. Blankets and quilts constitute the major part of the imports under paragraph 264.

In the nine months from October 4, 1913, to June 30, 1914, inclusive, the first period under the reduced tariff of 1913, the combined imports of cotton towels, bath mats, quilts, blankets, polishing cloths, mop cloths, wash rags or cloths, sheets, pillowcases and batting amounted to $343,507. If these imports were maintained at the same ratio for one year the total importations would have a value of $458,009 and the duties collected would be $85,864. The highest valuation was $593,472 in 1920, with $148,086 duties collected; imports in 1921 were valued at $410,341, and the duties collected (which includes additional duties under the emergency tariff of May 27), were $106,174.

TOWELS AND BATH MATS.

General Information.

Act of 1913, paragraph 264. Towels, bath mats, * * * any of the foregoing made of cotton or of which cotton is the component material of chief value, not embroidered nor in part of lace and not otherwise provided for, 25 per centum ad valorem.

DESCRIPTION.

Cotton towels may be divided into two general classes: (1) Pile fabrics, mainly terry woven goods, which are familiarly known as Turkish or bath towels; and (2) nonpile fabrics, mainly the ordinary huck or huckaback towels.

Terry cloth, from which Turkish towels are made, is woven with one filling and two sets of warps. The pile may cover the entire cloth, but usually it is woven with plain stripes at the head ends, where the towels are to be cut and hemmed, and frequently with a border of plain stripes or Jacquard figures. Bath mats and wash cloths are also made of terry cloth. Any of these articles may be made as pile fabrics on knitting machines, but as yet this has not been done very extensively.

The term huck or huckaback towels applies to fabrics woven in patterns such as bird's-eye or honeycomb, which have yarn floats of soft heavy filling to increase the absorptivity of the cloth. Harder twisted two-ply yarns are usually employed in the selvage. Union huck towels are made of cotton and linen, and as the linen is usually of greater value, the imports come principally under Schedule J.

Toweling is sold by the piece, by the yard, or by the towel. The finished towel is usually hemmed or hemstitched, with white or colored borders.

DOMESTIC PRODUCTION.

Materials.—The cotton used in making towels is usually of low and medium grades, spun into comparatively coarse yarns; for terry cloth the warps are generally 20/2 to 30/2 yarn and the fillings 20s to 30s. Yarns for huck toweling vary considerably; the body yarns are usually singles, while the selvage ends are two-ply. The latter yarns are given as little twist as is consistent with good weaving.

Equipment.—Turkish toweling is made on a loom having two warp beams and a special attachment for the terry motion; a Jacquard loom with a similar attachment is used for patterned material. A dobby loom with one warp beam and one shuttle is used for plain white huckaback towels; colored borders require a greater number of shuttles and a somewhat more complicated mechanism.

Methods of production.—For weaving terry cloth or Turkish toweling the ground warp is wound on one beam and the pile warp on a second beam with an easing arrangement which allows the yarn to remain slack. A number of picks are inserted and then beaten up, sliding

over the ground warp which is tightly stretched, but carrying the slack pile warp with them, thus forming a series of loops bound together by the filling picks. The terry motion can be thrown out of operation by the weaver, or by an automatic arrangement the loom can be made to produce terry-woven and plain toweling alternately for any desired length. When huckaback towels are to be finished with a fringe, the loom is fitted with a fringe motion which pulls the woven towel forward, leaving a space of warp threads without filling before the weaving of the next towel length is begun.

Organization.—The manufacture of towels is usually conducted in conjunction with other lines of weaving—crash, damask, sheeting, terry cloths, and others. There are about 70 establishments reported by the Official Textile Directory as manufacturers of cotton towels of one kind or another. A few of these, engaged primarily in other manufacture, are capitalized at over $1,000,000, but for the most part those whose principal output seems to be towels are small concerns operating from 50 to 60 looms or less. Although huck and terry-woven towels are sometimes made in the same establishments, huck towels are more often made by manufacturers of crash. One establishment, making both Turkish and huck towels, produces a large proportion of the entire output of the industry.

Geographical distribution.—The industry is centered in the South and East, a few concerns being reported from the middle West and only one from the Pacific Coast. The largest production is in North Carolina; Pennsylvania, New Jersey, and Georgia rank next.

Production and consumption.—Domestic production of Turkish towels and terry-woven toweling in 1919 was valued at $14,059,000. Furthermore, towels and toweling, wash cloths, bath mats, wiping and polishing cloths (except pile fabrics), all of which were not separately reported, had a combined value of $16,786,000 for the year 1919. It is estimated that plain towels and toweling and bath mats constitute a large portion of the value of the articles enumerated. The total quantity in 1914 amounted to 75,798,907 square yards, valued at $9,805,232, which was an increase in quantity of 44 per cent over 1909. At the tariff hearing held January 26, 1921, a leading manufacturer of terry fabrics stated that this industry operated about 6,000 looms, consumed annually about 24,000,000 pounds of cotton, and had a capacity for a product valued at about $20,000,000. There are no figures relative to the production of huck towels, but apparently foreign competition can not be very serious, as manufacturers have never appeared at tariff hearings.

EXPORTS.

Export figures are not given, but Canadian statistics show importations from the United States of cotton towels valued at $296,128 in 1919, and $400,974 in 1920, and of cotton toweling valued at $61,648 in 1919, and $61,380 in 1920.

TARIFF CONSIDERATIONS.

Terry cloth in the piece is dutiable under paragraph 257 at 40 per cent, while towels made of this material are dutiable under paragraph 264 at 25 per cent.

28762—22—I-8——2

IMPORTS.

For the nine months ended June 30, 1914, which was the first time that imports of cotton towels and bath mats were specifically mentioned, the value amounted to $154,325 although the rate of duty on these articles had been reduced from 45 to 25 per cent ad valorem. In no year since have imports reached a value of over $109,000, the average yearly importations since the act of 1913 amounting to $90,836. Prior to 1914 the foreign goods of this character coming into the United States could have been only a small proportion of the domestic output, as under the act of 1909 imports of all unenumerated cotton manufactures, under which classification towels would fall, never reached $2,000,000.

COTTON QUILTS.

General Information.

Act of 1913, paragraph 264. * * * Quilts * * * made of cotton, or of which cotton is the component material of chief value, not embroidered nor in part of lace and not otherwise provided for, 25 per centum ad valorem.

DESCRIPTION.

Quilts, also termed bedspreads, coverlets, and counterpanes, are used as bed covering. There are two main types, one having two sets each of warp and of filling yarns; the other having one set of warp and one set of filling yarns.

Marseilles quilts are made with large embossed designs, one of which is complete on each quilt. The cloth is double; that is, composed of two plain woven fabrics which are not united at the ground but which are interwoven at the figures, thereby producing the raised effect which is accentuated by the use of heavy filling as wadding. If the ground is of sufficient area, the two fabrics of which it is formed may be distinguished by rubbing the plain area between the fingers. The term "satin" when applied to cotton quilts refers to the structure although it is not what is technically known as satin weave. It also is a double cloth, not in the sense that any part is made up of two distinct fabrics but in that two sets of warp and two sets of filling yarns are used in its construction. A coarse filling floats over the ground yarns to form the pattern, and under the yarns when no pattern is required, making possible a reversible cloth if the design be planned with this end in view. When the ground is visible on one side, the heavy filling yarn will be visible on the other.

Crochet quilts have nothing in common with the ordinary work made with crochet needles. The term is given to a twilled or Jacquard single fabric woven with one set of warp and one set filling of medium or fine count yarns. The cheaper grades of quilts are usually of this structure. Honeycomb and Alhambra quilts are of the same class, differing principally in the type of design used.

Dimity spreads are made from plain woven fabrics having raised threads or cords running with the warp. These are cheaper than the quilts described because they are simpler to weave. The material is woven continuously like any similar broad-loom fabric and then cut to size and hemmed.

Ripplettes.—Bedspreads made of "ripple cloth" have been held dutiable as manufactures of cotton cloth, instead of cotton quilts, though their use is the same. This "ripple cloth" is made into bedspreads called "Ripplettes," which is a class of dimity spread made of thin cloth of sheeting texture having either cords or seersucker effect. It is not made on the Jacquard quilt loom, but on a common loom having two beams with different tensions; the beam with

a looser tension feeds the yarn to the loom faster than does the other beam, and in this way causes a ripple effect in the woven cloth. The demand for this class of goods is chiefly by hospitals where cheapness and the ease with which they may be laundered make them particularly desirable.

Comfortables.—These are sometimes spoken of in the trade as quilts or comforts. They are made with two layers of fabric between which is wadding or batting. The fabrics used are standard weaves of cloth having 32 to 36 warp threads per inch, and from 64 to 88 filling threads per inch; also sateen cloths with 64 to 104 threads per inch in the warp and 96 to 180 threads per inch in the filling. It is estimated that the domestic production of comfortables in 1920 was about 2,500,000.

Quilts vary in size from 92 to 108 inches for the larger ones, down to 28 by 63 inches for the crib size.

DOMESTIC PRODUCTION.

Value of output.—Statistics show that in 1919 bedspreads and quilts (Marseilles, satin, and crochet) were produced at a value of $10,245,000.

Materials.—The yarns used are of domestic origin, ranging from 3s to 80s, both single and ply, with the lower sizes predominating.

Equipment.—Jacquard looms are required for Marseilles, satin, and crochet quilts, but of somewhat different type in each case. Dimity bedspreads and "ripple cloth" are made on a plain, or else a dobby, loom. These various looms are built in the United States.

Methods of production.—The making of quilts is only one stage beyond the manufacture of the fabric. Weaving is the most important process and presents the same problem as for similar piece goods. As a rule, quilts are woven in the gray and then bleached and finished. The process subsequent to weaving will cause a quilt to shrink about 10 per cent in the width and to gain about 1 per cent in the length. After the quilts are bleached, starched, and blued, they are cut, and hemmed, scallopped or fringed, special machines being used for each operation.

Organization.—According to the Official Textile Directory for 1920, there are 20 concerns engaged in this line of manufacture. The capitalization ranges from $10,000 to $2,500,000, but the largest part of the output is undoubtedly by the heavily capitalized establishments, as the total number of looms operated by all the small concerns is not much greater than the number in one large mill. Other goods, such as sheetings, ginghams, and cotton damask, are often produced in conjunction with the manufacture of bedspreads. In some establishments, curtains, tapestries, and upholstery goods are made, while 11 are not reported as manufacturing other fabrics. The number of looms operating on this class of goods in the United States during 1920 was approximately 1,800.

Geographical distribution.—The New England States show more looms in the industry than any other section, with North Carolina probably second and Pennsylvania third. There are a greater number of establishments in Pennsylvania than in any other State, but it is not likely that their output exceeds in value that of other States, as the mills are small and do not manufacture quilts exclusively.

COMPETITIVE CONDITIONS.

Judging from import statistics, there is little foreign competition in cotton quilts or bedspreads, for although imports from 1914 to 1920 may have been small because of abnormal conditions, imports under the act of 1909 could not have amounted to a very formidable figure, as the largest value imported under the "basket clause," which included many other articles, was $1,813,205 in 1910. An importer made the statement that competition from domestic manufacturers has become so strong that foreign goods can not compete except on the very finest quality, usually of heavy weight, and these only in small lots bought by retail stores making a feature of imported goods. The importer asserts that the English quilts are superior in quality of yarn and in weave, but that this has little effect on their salability, as the largest consumers of imported goods are the hotels, where superior quality counts for less than the cheaper price of the American goods.

IMPORTS.

In statistics of imports cotton quilts are included with cotton blankets, and this classification begins only with the act of 1913. Available figures, representing years of unusual conditions, are not a very reliable index of foreign competition. Imports of cotton quilts and blankets were highest in 1920, being valued at $387,074; in 1921 they were valued at $230,862. The amount imported, however, is so small as not to be competitive with domestic manufacture. All the present imports of quilts are satin quilts with raised Jacquard figures. Marseilles quilts have gone out of style, and a true Marseilles has not been imported for years. Domestic manufacturers practically control the home market in the cheaper grades, so that few crochet quilts are imported. England is the most important source of foreign goods. (*See* table of imports on p. 9.)

EXPORTS.

Exports are not recorded, but are larger than imports. For instance, Canadian statistics for the fiscal year ended March 31, 1921, show imports from the United States of quilts and bedspreads valued at $235,932.

For Rates of Duty and Court and Treasury Decisions, see pages 15 and 16.

COTTON BLANKETS.

General Information.

Act of 1913, paragraph 264. * * * blankets * * * made of cotton, or of which cotton is the component material of chief value, not embroidered nor in part of lace and not otherwise provided for, 25 per centum ad valorem.

DESCRIPTION.

Blankets are napped fabrics, the nap being produced by a partial cutting and raising of the fibers. The processes have been so developed that a fabric entirely of cotton may be made to resemble wool, or given what is known as a "wool finish." The springy feel of wool is sometimes obtained by a partial use of Chinese cotton, which is coarser and more crinkly than American cotton. Three distinct types of cotton blankets are commonly produced—i. e., staple blankets, which are plain woven with colored borders; wool-finish blankets, having colored borders; and Jacquard figured blankets. The staple blankets are much cheaper than those of wool finish or the Jacquard figured. The principal operations in blanket manufacture consist of weaving, napping, cutting, and binding or finishing with an overedge stitch. The common larger sizes are 64 by 78 inches and 72 by 84 inches, while the crib sizes are 30 by 40 inches and 36 by 50 inches.

DOMESTIC PRODUCTION.

Materials.—Warp yarns used in blanket manufacture are usually between 15s to 20s and the filling yarns 2 to 6s; these are of domestic production and carded only. The looms used in weaving are of domestic manufacture. In the finished blanket the warp ends are usually from 38 to 50 per inch, while the filling picks vary from 26 to 48 per inch. Other cloths are usually made in conjunction with the manufacture of blankets, some of which may be napped goods, outing flannels, felts, shirtings, shoe twills, etc.

Organization.—Although there are about 13 manufacturers of cotton blankets in the United States, the bulk of production is by three or four concerns, each having a capitalization of from $1,000,000 to $3,500,000, while many of the others are capitalized at $300,000 or more. In 1919 the production of cotton blankets, of all kinds, was valued at $32,640,000, these being produced largely in the northeastern States; two mills having a relatively small production were situated in the Carolinas.

IMPORTS.

Import figures for cotton blankets are included in the statistics for cotton quilts. Together they amounted to a maximum value

of $387,074 in 1920 and $230,862 in 1921. Most of the importations consist of medium and high quality goods, and in general they are not sold as blankets, but are made up into fancy jackets, lounging robes, bath robes, etc. These have beautifully colored yarns running through the goods, and the finished articles sell for high prices.

Quantities were given, for the first time, in the last half of the calendar year 1918; during this period 10,328 cotton quilts and blankets valued at $37,544 were imported. Prior to 1914 imports of cotton blankets consisted largely of fancy Jacquard figured goods from Germany. Imports from Japan have increased but do not amount to a substantial proportion of the whole, Japanese statistics assigning them a value of only $6,300 in 1919.

Imports for consumption—Revenue.

[6] Average of 8¼ years.

EXPORTS.

Canadian statistics for the fiscal year ended March 31, 1921, give imports of cotton blankets from the United States valued at $257,622. Our exports of cotton quilts, blankets, and spreads to Canada amount to more than twice our imports of such articles from all sources.

POLISHING CLOTHS, DUST CLOTHS, MOP CLOTHS, WASH RAGS OR CLOTHS.

General Information.

Act of 1913, paragraph 264 * * * polishing cloths, dust cloths, mop cloths, wash rags or cloths * * * any of the foregoing made of cotton, or of which cotton is the component material of chief value, not embroidered nor in part of lace and not otherwise provided for, 25 per centum ad valorem.

DESCRIPTION.

Polishing cloths are small squares of napped cotton fabric, either 12 by 12 inches, or 18 by 18 inches, used in the household for polishing and dusting metal, glass, and wood; also in the harness trade and by the automobile-accessory business. Prior to 1914 these cloths were made with striped borders woven on four sides, but to-day the greatest demand is for cloths with colored borders, and hemmed only on two opposite sides. These cloths are generally made of medium and heavy weight flannels; velveteen is also employed in smaller quantity for polishing silverware. During 1920 the domestic product amounted to about 25,000 cloths, one company making more than one-half the total, the rest being produced by one or two other concerns.

Dust cloths are usually 19 by 20 inches and have a border on all four sides. In general, the border yarns are red and blue; the body fabric has white yarns in one direction, and orange-colored yarns in the other direction, giving the cloth a light orange appearance. These are made of light flannel and are not produced in the United States.

Mop cloths, sometimes called scrub cloths, are usually all cotton, and are about 20 by 20 inches in size. The warp yarns are very coarse with little twist; the filling yarns are almost one-eighth inch in diameter, and would be considered nearer a roving than a yarn. The squares are, in general, hemmed only on the two sides running parallel with the filling.

Wash rags or cloths, also called face cloths, are about 15 by 15 inches and made of terry woven cloth. The borders usually contain colored yarns; many cloths have colored yarns running in both the warp and filling directions, and woven in such a manner as to form squares throughout, and others are made with plain white yarns. The domestic manufacturers practically control the United States market.

IMPORTS.

Before the war the imports of polishing cloths and mop cloths, usually from Germany and Austria, were larger than domestic production, but to-day the domestic product is probably consumed in larger quantities than the imported.

Polishing cloths, dust cloths, mop cloths, and wash rags or cloths, classed together in the import statistics, ranged from a maximum value of $63,077, in 1914, to a minumum value of $7,023 in 1919. In 1921 the imports were valued at $31,614. It is probable that polishing cloths and dust cloths normally constituted a large part of the total. Imports were considerably increased in 1920 and 1921 over those of any year since 1915, which indicates a resumption of importation from Germany.

SHEETS AND PILLOWCASES.

General Information.

Act of 1913, paragraph 264. * * * sheets, pillowcases, * * * any of the foregoing made of cotton, or of which cotton is the component material of chief value, not embroidered nor in part of lace and not otherwise provided for, 25 per centum ad valorem.

DESCRIPTION.

Sheets.—Sheets are made from wide sheetings, which are plain woven cotton cloths varying in width from 36 to 90 inches; even greater widths are sometimes used. The cloth is bleached white, given a soft finish, then cut into suitable lengths and hemmed for use as bed sheets or sewed up for pillowcases. The 81-inch width probably predominates for sheets, and 45 inches for pillowcases.

Pillow tubing is woven on a loom, and differs from ordinary cloth in that it is woven as two cloths, one above the other, forming a continuous tube. This tubing is bleached, cut into required lengths, sewed up at one end, the other or open end is hemmed, and they are then ready for use as pillowcases or bolster covers. The tubing widths, as woven, vary from 18 to 24 inches, the largest consumption being 42 and 45 inches in circumference.

DOMESTIC PRODUCTION.

Materials.—In practically all sheets and pillowcases the yarn is carded only, the warp being made of about 21s and the filling from 25s to 30s; normal constructions are 64 by 64 to 72 by 72 ends per square inch. The cloth widths are usually from 36 to 90 inches, while the weights range from 3.50 to 1.30 yards, respectively, per pound. The most usual size sheet is 81 inches wide and 90 inches in length; the next largest sizes are 81 by 99, 72 by 90, 63 by 90, 90 by 99, and 90 by 108. In conjunction with the manufacture of sheeting, other cloths are produced—such as shirtings, sateens, chambrays, dress goods, drills, towels, crashes, ducks, and osnaburgs.

Production and consumption.—The domestic production is ample to supply all needs, as the value of sheets and pillowcases produced in the United States in 1919 amounted to $3,369,000; this has reference to only those mills that make up sheets and pillowcases from cloths they themselves produce. An article in the February 10, 1921, issue of the American Wool and Cotton Reporter states that there is a yearly domestic production of about 20,000,000 sheets, the total value of which is approximately $20,000,000. Pillow tubing, subsequently to be made into cases, amounted to 15,213,000 square yards, valued at $1,484,000 in 1914, and in the year 1919 the production was 12,113,000 square yards, valued at $2,555,000. Concerns primarily engaged in the production of sheetings are comparatively few; their capitalization ranges from $1,000,000 to $12,000,000 each.

Methods of production.—About one-sixth of the total production of sheets and pillowcases sold in the market is made in the mills

where the cloth is produced. There are also large concerns which buy the gray sheeting, bleach it, then have it torn and hemmed to suitable size. Smaller quantities of these goods are made, for their individual use, by women who purchase the gray or bleached sheeting from the stores.

Geographical distribution.—The sheet and pillowcase industry is not localized, although the New England States produce the bulk. A number of important establishments are located in Massachusetts, Rhode Island, New York, North Carolina, Virginia, and Alabama.

IMPORTS.

In the fiscal year 1914 the total imports of finished sheets and pillowcases not ornamented with lace or embroidery were valued at $4,836, while in the calendar year 1921 the maximum value—$38,309—was reached. These foreign goods are in demand mainly on account of their special finish and are seldom found outside the stores of leading import centers. They are sold in stores which carry a certain amount of imported goods and are willing to pay higher prices than are quoted for practically similar domestic goods. One large importing concern stated that the pillowcases were 22 by 36 inches, and sheets were 80 by 108 inches, the staple of cotton used being less than 1⅜ inches in length.

EXPORTS.

Sheets and pillowcases are not reported separately in our statistics, but Canadian statistics show imports of sheets and pillowcases from the United States for the fiscal year ended March 31, 1921, valued at $125,595.

For Rates of Duty and Court and Treasury Decisions, see pages 15 and 16.

COTTON BATTING.

General Information.

Act of 1913, paragraph 264. * * * batting * * * made of cotton, or of which cotton is the component material of chief value, not embroidered, nor in part of lace and not otherwise provided for, 25 per centum ad valorem.

DESCRIPTION AND USES.

Batting is cotton fiber in thick but lightly matted sheets. The largest quantities are probably consumed in the manufacture of comforts and mattresses, but there are many other important uses. Tailors often pad coats with batting or less frequently use it as a quilted interlining in overcoats, for which purposes it is dyed black. When a layer of batting is quilted between sheets of a thin fabric such as China silk it makes an admirably warm yet light material for coverlets and dressing gowns. Jewelers use considerable quantities of batting, either white or tinted, for packing their goods. A high-class batting with long fibers and little nap is preferred by this trade. By a removal of the natural wax which covers the cotton fiber, batting may be rendered absorbent. Large quantities are used in sanitary towels and surgical dressings.

DOMESTIC PRODUCTION.

Materials and processes.—The bulk of the cotton batting is used for stuffing and is made from low grade soft cotton waste. Finer qualities of waste or raw cotton are made into better grades. Batting material, after being opened and cleaned, is put through a card which has a special lap-forming attachment for superimposing the thin carded web to form any desired thickness. When wadding is required for special purposes, a gumming roller is employed to supply the gum or sizing; the webs are thereby made to adhere to each other. Most batting, whether gummed or ungummed, is sold without further processing. Some batting is bleached, dyed, or processed to make it absorbent, aseptic, or antiseptic. Medicated battings and battings impregnated with substances effective in cleaning and polishing are sold under proprietary and patented names and have gained a regular trade through advertising.

Organization.—In a study of the international trade in cotton batting the Department of Commerce states:[1] "The figures for batting are not given separately, but if available they would doubtless indicate that the first place in this industry also belongs to the United States." The Official Textile Directory lists 138 manufacturers of this commodity and as many of these are makers of bedding, mattresses, or carpet linings, they undoubtedly consume a large proportion of the total production. Besides the cotton batting used in industries, some is put up in small packages for the retail trade.

[1] Department of Commerce, Special Consular Reports No. 80, p. 7.

IMPORTS.

Sources and consumption.—The quantity of cotton batting imported has increased from 42,102 pounds, valued at $4,378 in 1914, to 196,498 pounds, valued at $38,897 in 1921. Most of this is made in Japan, a small amount in China, and it is all shipped direct to Hawaii, none coming to the continental United States.

[1] From October 4, 1913, to June 30, 1914, inclusive.
[2] Fiscal year ended June 30.
[3] July 1, 1918, to December 31, 1918, inclusive.
[4] Calendar years.
[5] Average of 8¼ years.

EXPORTS.

Statistics show that our exports of cotton batting to Canada alone have been much greater in every year than our imports of that product from all countries, and that for the years mentioned exports almost equaled total imports. From Canadian official figures for the year ended March 31, 1921, the imports of batting from the United States were 121,920 pounds, valued at $36,637. Important cotton manufacturing countries such as Germany and England produce large quantities of cotton batting or wadding. Germany exports considerable quantities, but as yet has sent very little to the United States.

RATES OF DUTY.

1913	264	Towels, bath mats, quilts, blankets, polishing cloths, mop cloths, wash rags or cloths, sheets, pillowcases, and batting, any of the foregoing made of cotton, or of which cotton is the component material of chief value, not embroidered nor in part of lace and not otherwise provided for.	25 per cent ad valorem.
1921	17	Manufactures of which cotton of the kind provided for in paragraph 16 is the component material of chief value (in addition to the rates of duty imposed thereon by existing law. (Par. 16 provides that cotton having a staple of 1⅛ inches or more in length shall be dutiable at 7 cents per pound.)	7 cents per pound.

COURT AND TREASURY DECISIONS.

(The articles covered by paragraph 264 of the tariff act of 1913 were previously classified as manufactures of cotton.)

Paragraph 264 of the act of 1913 includes towels of cotton woven on Jacquard looms (G. A. 7609, T. D. 34819, of 1914); Turkish towels (G. A. 7656, T. D. 35019, of 1914, 8 Ct. Cust. Appls., 150, of 1917); bath mats and quilts of cotton cloth woven on Jacquard looms (G. A. 7748, T. D. 35577, of 1915); cotton blankets woven on Jacquard looms (Abstract 37475, of 1915); cotton drawnwork sheets and pillowcases not embroidered or in part of lace, but having at the edge of the hem threads drawn and additional threads inserted forming an ornamental openwork effect (Abstract 38774, of 1915); Turkish towels in the piece woven in patterns in such a manner that each towel is distinctly set forth and a few plain threads are inserted at regular intervals showing where the articles are to be cut apart (G. A. 7673, T. D. 35101, of 1915); polishing cloths of cotton velvet (Abstract 41604, of 1917); and cloths reported by the appraiser as dust cloths found to be polishing cloths (Abstract 42786, of 1918).

Coverings of ripple cloth to protect blankets from dirt are not "sheets" (G. A. 7963, T. D. 36689, of 1916), and sanitary napkins, of batting and gauze, labeled "Emergency towel" are not "towels" (Abstract 37626, of 1915).

Cotton quilts trimmed with fringe were held to comé within paragraph 264 (Abstract 42029, of 1918, and 43977 and 44266, of 1921). But merchandise invoiced as chamois dusters, reported by the appraiser to be dust cloths composed of cotton, was held to come within paragraph 266 of the act of 1913 (Abstract 43965, of 1920). Later, merchandise invoiced as chamois dusters and classified as articles of cotton cloth under paragraph 266 was held to come within paragraph 264 as claimed (Abstract 44433, of 1921).

Merchandise classified as Jacquard-figured upholstery goods under paragraph 258 was held dutiable under paragraph 264 as cotton towels (Abstract 45080, of 1922).

PREFACE

This is one of a series of Tariff Information Surveys prepared by the United States Tariff Commission. These surveys have been prepared in accordance with the provisions of the tariff act in force at the time of their preparation and cover all the articles and commodities provided for in the acts of 1913 and 1922, together with others not specially provided for.

In some cases two or more paragraphs have been combined in one survey. In doing this, industrial relationship of the articles has been followed when possible. In those instances where an article or a commodity has been treated under a preceding paragraph reference to this fact is made. In cases where one grade of an article or commodity is dutiable and another grade of the same article or commodity is on the free list the entire subject is treated under the dutiable paragraph.

A separate pamphlet listing the principal subjects investigated and reported upon has been published. It contains:

(1) An alphabetical index of the articles and commodities provided for in the tariff acts of 1913 and 1922, showing the paragraph in the acts in which the article or commodity is provided for and, if discussed under a different paragraph, the number of such paragraph.

(2) The number of the survey in which the article or commodity is discussed.

Special and miscellaneous reports, unnumbered, are also included in the index.

Thus, by the use of the index, the exact location of the survey or report relating to a given article or commodity can be ascertained.

In the preparation of this report the Tariff Commission has had the services of A. H. McCarrel, of the textile division of the Commission's staff, and of others.

COTTON SMALL WARES

TARIFF ACT OF SEPTEMBER 21, 1922

Par. 913. Fabrics with fast edges not exceeding 12 inches in width, and articles made therefrom; tubings, garters, suspenders, braces, cords, tassels, and cords and tassels; all the foregoing composed wholly or in chief value of cotton or of cotton and india rubber, and not specially provided for, 35 per centum ad valorem; spindle banding, and lamp, stove, or candle wicking, made of cotton or other vegetable fiber, 10 cents per pound and 12½ per centum ad valorem; boot, shoe, or corset lacings, made of cotton or other vegetable fiber, 15 cents per pound and 20 per centum ad valorem; loom harness, healds, and collets, made wholly or in chief value of cotton or other vegetable fiber, 25 cents per pound and 25 per centum ad valorem; labels for garments or other articles, composed of cotton or other vegetable fiber, 50 per centum ad valorem; belting, for machinery, composed wholly or in chief value of cotton or other vegetable fiber, or cotton or other vegetable fiber and india rubber, 30 per centum ad valorem.

SUMMARY

DESCRIPTION

Paragraph 913 is known as the small wares paragraph of the cotton schedule of the act of 1922. Although confined mainly to fabrics with fast edges, not exceeding 12 inches in width, which are generally the products of narrow-ware looms, it includes certain types of machine belting that may be woven on wide or fly-shuttle looms, and a few articles made by braiding or by twisting.

Fabrics, with fast edges, not exceeding 12 inches in width is an inclusive term used to distinguish narrow-woven fabrics from cloth, which is over 12 inches in width. Such narrow wares include, without specific mention, bandings, beltings, bindings, ribbons, strappings, tapes, webbings, etc. *Articles made therefrom* include bands, belts, brake linings, girths, gun slings, straps, webs, etc.

Tubings are tubular woven products of the narrow-ware loom, and are used in stem work in the manufacture of artificial flowers; also as bone casings in corsets, and for other purposes.

Garters, suspenders, and braces are made from narrow wares, mainly from elastic and nonelastic webbings. Some braided elastics are also used.

Cords are made by braiding, or by cabling or twisting together two, three, or more strands or threads.

Tassels are pendant ornaments terminating in tufts of loose strands or threads, matching the cords to which they are to be attached.

Cords and tassels are combinations of cords and tassels.

Spindle banding is used on spinning, spooling, and twisting frames for transmitting power to the spindles. One type is made by twisting together strands of yarn or hard roving; another by braiding, while still others coming largely into use are woven on narrow-ware looms in the form of tape.

Lamp, stove, and candle wickings are made of cotton. For candle wicking, strands of cotton yarn are twisted or braided together

Lamp and stove wicking is made on braiding machines or woven on narrow-ware looms.

Boot, shoe, and corset lacings may be round, flat, or tubular, and are generally produced on braiding machines.

Loom harness consists of a number of *healds*, which are individual units of twine, assembled on frames and used on looms in the process of weaving, each *heald* containing an eye and carrying one thread, or unit, of the warp. The harness sustains the warp properly in the loom, and through it the shedding motion is transmitted to the warp. *Collets* are cords used on the loom for holding the harness in position.

Labels for garments or other articles are woven on narrow-ware or ribbon looms with Jacquard attachments.

Belting for machinery includes narrow textile woven beltings produced on narrow-ware looms and wide textile belts woven on heavy fly-shuttle looms. They are woven in different plies and weights, depending upon the intended use. Most of these woven belts are subsequently treated to render them waterproof or to improve their wearing qualities. Some are made by cutting, folding, and stitching together several plies of cotton canvas, duck, or twill. One type, known as "rubber belting," is made by impregnating canvas, duck, or twill cotton cloth with india rubber, folding and stitching, calendering between hot rollers under pressure, and vulcanizing. Another type is treated in the same manner with balata gum, but not vulcanized. Imports of cotton transmission rope are also classed as belting for machinery.

THE DOMESTIC INDUSTRY

History.—Little is known as to the early history of the domestic cotton small-wares industry. The output was not separately recorded by the census prior to 1899. It is probable that early manufacturing was confined to elementary staple articles, such as plain tapes, and was begun by plants making yarns and cloth. As the industry developed, separate plants were built and a greater variety of articles produced. With the introduction of mercerized cotton yarns, artificial silk, and the highly developed manufacture of elastic webbings, some lines of narrow woven fabrics are now as much subject to fashion as are wide fabrics, thousands of new designs being introduced each year. The development of the manufacture of small wares as an industry, by plants engaged primarily in their production, has kept pace with that of staple textiles.

In the several States manufacturing small wares in appreciable amounts, plants were established in the following chronological order:

Rhode Island, 1824, 1864, 1873, 1883, 1885.
Maryland, 1825, 1848.
Pennsylvania, 1827, 1888, 1893.
Connecticut, 1834, 1837, 1856, 1914.
Massachusetts, 1854, 1860, 1863, 1865, 1870, 1876.
New York, 1867.
Ohio, 1875, 1897.
New Jersey, 1883, 1886, 1890, 1892, 1893.
Indiana, 1884.
Michigan, 1891.
Georgia and Illinois, one each in the year 1896.

North Carolina, 1897.
Oklahoma, 1906.

Production.—The census classification of small wares does not coincide with the group of articles listed in what is known as the "small-wares paragraph" in import statistics, the latter being wider in scope than the former. Small wares, specified as such by the census, were valued at $11,525,033 in 1914, $40,896,835 in 1919, and $26,061,193 in 1921. In addition there were produced suspenders, garters, and elastic woven goods to the value of $24,432,753 in 1914, $60,774,652 in 1919, and $44,935,467 in 1921; rubber belting to the value of $22,436,242 in 1919, and $13,068,798 in 1921. While hose is not included in the small-wares paragraph, the combined value of belting and hose other than leather and rubber was $19,176,277 in 1919 and $6,390,498 in 1921. Of the latter amount, $3,288,708 was recorded as the value of woven belting. The high values shown for 1919 are due to the enhanced prices then prevailing rather than to increase in volume of output.

TABLE 1.—*Cotton small-wares industry—Production, census years 1904–1921*

Yarns for sale:					
Pounds	162,000	150,428			
Value	$54,300	$96,279			
Yarns produced:					
Pounds	[5] 2,410,268	[5] 2,637,021	[5] 9,185,556		
No. 20 and under, coarse	344,135	1,127,514			
No. 21 to No. 40, medium	2,066,133	1,432,464			
No. 41 to No. 60, fine		77,043			

[1] In addition, cotton small wares to the value of $1,572,120 in 1921, and $5,735,069 in 1919, were reported by establishments engaged in other branches of the cotton-manufactures industry, or in other industries. Of these amounts, $933,997, in 1921, and $4,182,888 in 1919, represent the value of cotton small-wares reported by establishments classified in the cotton-goods branch of this industry.
[2] Does not include spindle banding to the value of $424,000 not reported in yards.
[3] Not reported in 1919.
[4] In 1919 included in "All other products."
[5] Including that used in the further process of manufacture.

Owing to changes in the census classification of the cotton small-wares industry, the 1923 data are not comparable with those for previous years. The following tabulation of preliminary figures shows the value of articles grouped as small wares in 1923:

TABLE 1a.—*Cotton small-wares industry—Production, 1923*

[Preliminary figures]

Total value of products	$73,223,566
Belting	1,775,503
Elastic webbing	25,774,024
All other woven cotton small wares	17,633,670
Braided cotton small wares	14,659,205
All other cotton small wares	13,381,164

Of the $73,223,566 reported as the value of small wares in 1923, $33,818,643 represented the output of 54 establishments classified in 1921 as manufacturers of "Belting and hose, other than leather and rubber" and "Suspenders, garters, and elastic webbing." Deducting the $33,818,643 from the total reported for small wares gives $39,404,923, a figure which is fairly comparable with the 1921 total of $26,061,193, and which represents an increase of 51.2 per cent.

Prior to 1899 the census included the cotton small-wares industry with "cotton goods." The decrease shown from 1909 to 1914 was partly due to the inclusion in the 1909 classification of some establishments engaged in the manufacture of cotton lace, which, in 1914, were assigned to the cotton lace industry. Then, too, a number of large establishments formerly classed in the cotton small-wares industry by 1914 had so changed their products that cotton small wares no longer constituted their product of chief value. The census of 1919 showed a considerable increase, the value of products being then two and a half times greater than in 1914. The increase, however, was due in great measure to the higher prices prevailing in 1919 and is not to be attributed wholly to increased production. A decrease was shown for 1921 as compared with 1919, the value of the 1921 production falling 37.4 per cent below that for 1919.

Geographical distribution.—Cotton small wares were first separately recorded in 1899. Table 2 shows, by States, comparative statistics of the domestic industry for the census years 1899 to 1921. The figures in this table include, in addition to the data for articles covered by paragraph 913 of the tariff act of 1922, statistics for certain articles such as fancy braids (Barmen lace) dutiable under other paragraphs.

A standard textile directory (Davison's) for 1924, in the classification of cotton mills, lists domestic plants as follows:

State	Bandings	Braids	Shoe and corset laces	Shoe gorings	Narrow fabrics	Webbing, elastic and non-elastic	Wicking	Woven labels
Alabama	1	1			1		1	
California								1
Connecticut	3	10	1		8	12	3	1
Delaware		1						
Georgia	3				1	2		
Illinois		2	2		1	1	1	
Indiana					1	1	1	
Kentucky	1		1		1		1	
Maine		1						
Maryland	1	1				2		
Massachusetts	6	20	21	3	26	30	6	
Michigan					1			
Missouri			2					
New Hampshire		4	1		5	1		
New Jersey	4	6	3		3	8		9
New York		10	4		11	6	2	4
North Carolina		2	1		1	1		
Ohio	1	1	2		1	3	1	
Pennsylvania	6	15	7		26	11	2	1
Rhode Island	1	40	35		30	20	2	1
Tennessee							1	

Plants are not confined strictly to the one line indicated in the above tabulation; many large plants turn out a diversity of products.

Organization.—Tables 2 and 3 show the number of establishments, persons employed in the industry, salaries and wages, capital invested, costs of materials, and value of products, 1899 to 1921.

TABLE 2.—*Cotton small-wares industry—Comparative statistics by States, census years, 1899–1921*

[Source: Federal Census]

State	Census year	Number of establishments	Persons engaged in the industry				Primary horsepower	Expressed in thousands of dollars

[1] Figures for 1921 do not include establishments reporting products below $5,000, thus excluding seven establishments employing 10 wage earners and reporting products amounting to $20,000. The figures for 1919, however, include one establishment of this class.

[2] Capital not recorded.

[3] Percentage based on data indicated by footnote 2.

[4] Exclusive of internal revenue.

[5] In addition, cotton small wares to the value of $1,572,120 in 1921 and $5,735,069 in 1919 were reported by establishments engaged primarily in other branches of cotton manufactures or in other industries. Of these amounts, $933,997 in 1921 and $4,182,888 in 1919 represent the value of cotton small wares reported by establishments classified in the cotton-goods branch of the industry.

[6] Value of products less cost of materials.

Owing to changes in classification, organization data as reported by the Census for 1923 are not comparable with 1921 and other earlier figures, and are therefore here shown separately.

TABLE 3a.—*Cotton small wares—Organization, 1923*

Number of establishments	228
Persons engaged	17,902
Proprietors and firm members	117
Salaried employees	1,398
Wage earners, average number	16,387
Horsepower	32,458
Salaries and wages	$19,733,651
Salaries	3,776,777
Wages	15,956,874
Cost of materials	38,614,695
Value of products	73,223,566
Value added by manufacture	34,608,871

Materials used.—Cotton yarns were the principal material used in the manufacture of cotton small wares in the early stages of the industry; this is still the case, but with the introduction of mercerizing, and the use of silk, artificial silk, and rubber elastic threads and strands, the products have become more diversified. As previously stated, narrow-woven fabrics are as much subject to fashion as other fabrics, many new designs being introduced in the market each year; and, aside from the dictates of fashion, new types are being constantly demanded by inventions and the arts.

Table 4 shows the materials used in the manufacture of cotton small wares in each census year since 1904.

All other materials: Cost	$518,840	$1,065,060	$938,774	$3,930,280	(2)

[1] Figures for 1923 are omitted as they are not comparable because of changes in classification.
[2] Figures for subdivision not available.
[3] Included in "All other materials," in order to avoid disclosure of individual operations.
[4] Not reported separately.

EXPORTS

Exports of cotton small wares are not shown separately, but they are known to be larger than imports. The extent of the export trade is indicated by Table 5, which gives Canadian imports of cotton small wares from the United States for the fiscal years ended March 31, 1911 to 1924, inclusive. In 1924 more than 72 per cent of cotton small wares imported by Canada came from the United States.

Exports of rubber belting from the United States are widely distributed.

TABLE 5.—*Cotton small wares: Canadian imports from the United States of sundry small wares and percentage which the imports of each article or group of articles forms of total Canadian imports of such article, 1911–1924*

Ribbons, undyed, for typewriter ribbons	$21,370	38.8	$9,400	17.4
Belting of cotton	56,122	71.1	57,962	64.3
Boot, shoes, shirt, and stay laces, any material	110,527	72.3	82,119	58.9
Braces, suspenders, and finished parts of	59,561	72.9	65,316	70.5
Lamp wicks	31,970	80.0	38,190	90.6
Tape of cotton, not over 1¼ inches in width	143,654	52.7	132,354	48.1
Tape, not dyes, or colored	28,354	78.4	17,955	76.0
Webbing, elastic, over 1 inch wide	333,518	95.0	291,988	93.5
Webbing, nonelastic, for suspenders	4,344	100.0	4,705	95.5
Tape, dyed or colored	20,885	87.5	23,437	98.0
Fabric of duck, cotton, or linen, circular woven, seamless, for the manufacture of hose	142,705	100.0	170,207	98.0

IMPORTS

Scope of cotton small-wares paragraph.—The tariff chart herewith presented shows the articles specifically mentioned in the cotton small-wares paragraphs of the several tariff acts since 1883. It will be noted that the tendency has been to widen the scope of the paragraph to include all cotton small wares and manufactures therefrom. The act of 1922 incorporates in paragraph 913 the most comprehensive grouping yet effected. Except where it was deemed necessary to take precaution against litigation, or where the adoption of special rates was desired, eo nomine designation has been intentionally omitted. Under the inclusive wording "fabrics with fast edges not exceeding 12 inches in width, and articles made therefrom" provision is made for narrow wares specifically mentioned in previous tariff acts, such as bandings, bindings, beltings, ribbons, tapes, and webbing. Braids, galloons, and gimps, which were included with small wares in the acts of 1883, 1890, and 1894, are separately provided for in paragraph 1430 of the act of 1922. Tire fabric, or fabric suitable for pneumatic tires, included in the small-wares paragraph of the acts of 1909 and 1913, is specifically provided for in paragraph 905 of the act of 1913 as a cloth or wide fabric.

[1] Jan. 1 to Sept. 21, inclusive.
[2] Sept. 22 to Dec. 31, inclusive.
[3] Preliminary figures.
[4] Fabrics not exceeding 12 inches in width and articles made therefrom.

COMPETITIVE CONDITIONS

The domestic small-wares industry is firmly established. Competitive imports are mainly from Germany, and consist of ribbon and other narrow-ware loom products. Germany has a highly developed industry, centering in Barmen and vicinity, and, as compared with the United States, has cheaper dyes and lower labor costs.

RATES OF DUTY

TABLE 8.—*Cotton small wares (general, inclusive)—Rates of duty, 1883-1922*

Act of—	Paragraph	Tariff classification or description	Rate of duty
1883	324	Cotton cords, braids, gimps, galloons, webbing, goring, suspenders, braces, * * *.	35 per cent ad valorem.
1890	354	Cotton cords, braids, boot, shoe, and corset lacings	35 cents per pound.
		* * * cotton gimps, galloons, webbing, goring, suspenders and braces, any of the foregoing which are elastic or nonelastic.	40 per cent ad valorem.
		Provided, That none of the articles included in this paragraph shall pay a less rate of duty than.	Do.
1894	263	Cords, braids, boot, shoe and corset lacings, tapes, gimps, galloons, webbing, goring, suspenders and braces, woven, braided, or twisted lamp or candle wicking, lining for bicycle tires, spindle binding, any of the above made of cotton or other vegetable fiber and whether composed in part of India rubber or otherwise.	45 per cent ad valorem.
1897	320	Bandings, beltings, bindings, bone casings, cords, garters, lining for bicycle tires, ribbons, suspenders, and braces, tapes, tubings and webs or webbing, any of the foregoing articles made of cotton or other vegetable fiber, whether composed in part of india-rubber or otherwise, and not embroidered by hand or machinery.	Do.
		* * * spindle banding, woven, braided or twisted lamp, stove, or candle wicking made of cotton or other vegetable fiber.	10 cents per pound and 15 per cent ad valorem.
		* * * loom harness or healds made of cotton or other vegetable fiber, or of which cotton or other vegetable fiber is the component material of chief value.	50 cents per pound and 25 per cent ad valorem.
		* * * boot, shoe, and corset lacings made of cotton or other vegetable fiber.	25 cents per pound and 15 per cent ad valorem.
		Labels, for garments or other articles, composed of cotton or other vegetable fiber.	50 cents per pound and 30 per cent ad valorem.
1909	330	Bone casings, garters, tire fabric or fabric suitable for use in pneumatic tires, suspenders and braces, and tubing, any of the foregoing made of cotton or other vegetable fiber, and india rubber, or of which cotton or other vegetable fiber is the component material of chief value, and not embroidered by hand or machinery.	45 per cent ad valorem.
		* * * spindle banding, woven, braided or twisted lamp, stove, or candle wicking made of cotton or other vegetable fiber.	10 cents per pound and 15 per cent ad valorem.
		* * * loom harness, healds or collets made of cotton or other vegetable fiber, or of which cotton or other vegetable fiber is the component material of chief value.	50 cents per pound and 25 per cent ad valorem.

TABLE 8.—*Cotton small wares (general, inclusive)—Rates of duty, 1883–1922*—Continued

Act of—	Paragraph	Tariff classification or description	Rate of duty
1909	330	* * * boot, shoe, and corset lacings made of cotton or other vegetable fiber.	25 cents per pound and 15 per cent ad valorem.
		* * * labels, for garments or other articles, composed of cotton or other vegetable fiber.	50 cents per pound and 30 per cent ad valorem.
		* * * belting for machinery made of cotton or other vegetable fiber and india rubber, or of which cotton or other vegetable fiber is the component material of chief value.	30 per cent ad valorem.
	349	* * * bands, bandings, belts, beltings, bindings, cords, * * * ribbons, tapes, webs, and webbings; * * * all of the foregoing, composed wholly or in chief value of cotton, * * * or other vegetable fiber, or of cotton, * * * or other vegetable fiber and india rubber, or of cotton, * * * or other vegetable fiber, india rubber, and metal, and not elsewhere specially provided for in this section. *Provided*, That no article composed wholly or in chief value of one or more of the materials or goods specified in this paragraph, shall pay a less rate of duty than the highest rate imposed by this section upon any of the materials or goods of which the same is composed: * * *	60 per cent ad valorem
13	262	Bandings, belts, beltings, bindings, bone casings, cords, tassels, cords and tassels, garters, tire fabric or fabric suitable for use in pneumatic tires, suspenders and braces, and fabrics with fast edges not exceeding 12 inches in width, all of the foregoing made of cotton or other vegetable fiber, or of which cotton or other vegetable fiber is the component material of chief value, or of cotton or other vegetable fiber and india rubber, and not embroidered by hand or machinery; spindle banding, woven, braided, or twisted lamp, stove, or candle wicking made of cotton or other vegetable fiber; loom harness, healds, or collets made of cotton or other vegetable fiber, or of which cotton or other vegetable fiber is the component material of chief value; boot, shoe, and corset lacings made of cotton or other vegetable fiber; and labels for garments or other articles, composed of cotton or other vegetable fiber.	25 per cent ad valorem
		* * * belting for machinery made of cotton or other vegetable fiber and india rubber, or of which cotton or other vegetable fiber is the component material of chief value.	15 per cent ad valorem.
1922	913	Fabrics with fast edges not exceeding 12 inches in width, and articles made therefrom; tubings, garters, suspenders, braces, cords, tassels, and cords and tassels; all the foregoing composed wholly or in chief value of cotton or of cotton and india rubber, and not specially provided for.	35 per cent ad valorem
		* * * spindle banding, and lamp, stove, or candle wicking, made of cotton or other vegetable fiber.	10 cents per pound and 12½ per cent ad valorem.
		* * * boot, shoe, or corset lacings, made of cotton or other vegetable fiber.	15 cents per pound and 20 per cent ad valorem.
		* * * loom harness, healds, and collets, made wholly or in chief value of cotton or other vegetable fiber.	25 cents per pound and 25 per cent ad valorem.
		* * * labels for garments or other articles, composed of cotton or other vegetable fiber.	50 per cent ad valorem.
		* * * belting, for machinery, composed wholly or in chief value of cotton or other vegetable fiber, or cotton or other vegetable fiber and india rubber.	30 per cent ad valorem.

NOTE.—The words "spindle binding," appearing in paragraph 263 of the act of 1894 as reproduced in Table 8 above, is obviously a typographical error. The correct spelling is of course "banding."

I. NARROW FABRICS—FABRICS WITH FAST EDGES NOT EXCEEDING 12 INCHES IN WIDTH, AND ARTICLES MADE THEREFROM

General Information

DESCRIPTION

"Fabrics with fast edges not exceeding 12 inches in width, and articles made therefrom" is the inclusive term used in paragraph 913 of the tariff act of 1922 to describe narrow wares as distinguished from cloth, which may be defined as woven fabrics over 12 inches in width.

Narrow wares of cotton include tapes and webbings, plain or fancy; typewriter ribbons woven with fast edges; bandings; beltings; bindings; strappings; elastic webbings; surgical webbings; automobile brake linings, etc. Manufactures of narrow wares include hat bands; belts; girdles for women and children; boot and shoe straps; baby bands; cigar bands; back bands; saddle girths; gun slings; cartridge belts, etc. Excluded from the above, but only by reason of specific mention, are garters, suspenders, and braces; woven spindle banding; woven wicking; woven labels; and woven belting, not exceeding 12 inches in width, used in connection with machinery. Narrow strips cut from cotton cloth, such as cut tapes used for ordinary typewriter ribbons, are excluded from the classification by reason of the specification as to fast edges; imports of these are dutiable at the rates provided for the cloth from which they are cut.

Narrow wares of cotton include not only plain goods but many fancy and special fabrics. These, together with innumerable articles made from narrow wares, are subject to the continuous demands of fashion for new styles and variations. Manufacturers are therefore necessarily equipped to supply wide ranges of widths, weights, and designs. One of the largest domestic companies in this business is reported to have in its files the details and samples of over forty thousand distinct articles.

EQUIPMENT

In 1899 there were reported 42,600 spindles; in 1904, 39,530; and in 1909, 29,808. The total of 4,973 looms in 1919 and 160,007 divisions showed an average of 32 divisions for each narrow-ware loom.

Table 9 shows the equipment used in the cotton small-wares industry in the years 1914 and 1919.

TABLE 9.—*Cotton narrow wares—Equipment, census years 1914 and 1919* [1]

[Source: Federal Census]

[1] Not shown by census reports for 1921 and 1923.
[2] Mills in this industry reported 71,758 spindles in 1914; 29,808 in 1909; 39,530 in 1904; and 42,600 in 1899.
[3] Not including 1,600 mule-spinning spindles idle entire year.

In establishments producing cotton narrow wares, cotton yarns are the principal material. Although plants turning out diversified products in many instances spin coarse and medium yarns for their own use, the great majority of firms engaged in the manufacture of narrow-woven fabrics purchase all yarns used. For this reason no statistics are available for any other machinery than the narrow-ware looms and spindles, which prior to 1921 include twister spindles. The small-wares classification of the census includes articles of several types made by braiding; statistics show the number of braiding machines, with carriers, in use. These figures are shown in Section XI.—Braids, other than Barmen lace.

Census reports state that a number of large establishments previously classed in this industry had so changed their production by 1914 that cotton small wares had ceased to be their product of chief value.

In four of the largest domestic plants manufacturing diversified cotton small wares, including elastic and nonelastic webbings, braids, etc., all the equipment, both looms and braiders, are of domestic manufacture.

MATERIALS USED

In the general run of heavy narrow wares, such as narrow textile beltings, webbings, coarse tapes, elastic webbings, reins, etc., cotton yarns of low and medium counts are used. Although the majority of manufacturers purchase all yarns used, some manufacture the yarns for use in their products.

One of the oldest and largest plants, on a diversified line, produces its coarser yarns, up to No. 16, but purchases yarns above that number. This company does not import any yarns, but buys them, as well as all rubber strands used, from domestic manufacturers.

Another large company, operating three plants, also manufactures the coarser yarns for its own consumption, using an average of 150 bales of cotton per week. This company uses yarns of mercerized

cotton, artificial silk, and silk, and purchases its artificial silk from domestic manufacturers.

In another large narrow-wares plant, equipped with over 1,200 narrow-ware looms in addition to its braiding machinery, neither carding nor spinning is done, the company buying all yarns used, whether of cotton, mercerized cotton, linen, worsted, jute, silk, or artificial silk. Using cotton yarns ranging from 4s to 200s, two-ply, this firm purchases domestic yarns in the lower numbers and imports from England those above the range of the domestic market, from 120s two-ply to 200s two-ply, some in the grey but the greater portion gassed, bleached, and prepared. Some years ago this concern bought, for use in its elastic fabrics, large lots of imported Egyptian cotton yarns, 78s two-ply, but now, owing to the progress made in the fine cotton yarn industry in the South, it uses southern 80s two-ply. The fine imported yarns necessarily used in weaving the finest types of narrow wares are fully described in Section IX.—Labels for garments.

In the domestic market it is possible to obtain 100s two-ply gassed and bleached yarn that will weave well, and will be white, but such yarn is not "prepared." In the operation of "preparing," the yarn is rendered smooth and flexible, and at the same time is condensed by passing it a number of times between heavy calender rolls. The yarn may or may not be gassed. It is usually lubricated during the process, and for certain purposes it is also treated with sizing. All "prepared" yarns are imported from England as the "preparing" process is not used in this country. At present the firm referred to in the preceding paragraph is using no polished yarn ("Eisen Garn") or linen. Its pure silk materials are purchased in the domestic market and its fast-dyed red and blue yarns are imported. It uses artificial silk for filling in the weaving of elastic garter webbings and neckties. With the purpose of meeting competion in its exports to certain countries, this firm imports its artificial silk from Belgium, France, Italy, England, Switzerland, and the Netherlands, and obtains a drawback on the duty paid on the imported material used in its exports. The imported artificial silk arrives in the bleached condition and is dyed in the plant. Its quality is satisfactory, and its landed price is about the same as that quoted for the domestic article. The firm imports tinsel threads, but uses domestic elastic rubber strands.

To sum up: As used in the domestic manufacture of cotton small wares, the cotton yarns, in the coarser numbers, single and ply, are domestic products, and in some cases are produced in the small-wares plants. Grey, bleached, and mercerized cotton yarns, in the finer numbers, up to 100s, are generally of domestic manufacture. In numbers still finer, up to 200s two-ply, gassed, bleached, and prepared, manufacturers depend upon imports, domestic spinners not caring to accept orders for these. In products requiring fast Turkey-red and blue yarns that will stand bleaching and laundering, without fading or bleeding, imported materials are preferred. For special purposes, black polished yarn ("Eisen Garn" or "iron yarn") is imported. Metal tinsel threads are also imported, while rubber elastic strands are purchased in the domestic market. Artificial silk yarn is imported by some manufacturers under drawback privileges, to be taken advantage of in subsequent exports. While some

domestic manufacturers claim superior qualities for imported artificial silk, others find the domestic article satisfactory. Artificial straw, a product of cellulose, is both imported and of domestic manufacture.

METHODS OF PRODUCTION

Fabrics with fast edges, not exceeding 12 inches in width, are woven on narrow-ware looms, which produce a number of units simultaneously by means of small shuttles positively driven. The number of divisions or weaving units per loom, dependent upon the type of fabric and the loom adapted thereto, ranges approximately from 2 to 60, and possibly higher, with double-deck looms on the narrowest articles.

The first narrow-ware looms used in the domestic industry, known as tape looms, varied as little in their construction as did the narrow-woven fabrics. As the small-wares industry expanded, innumerable designs, types, and constructions of fabrics have resulted, and the consequent demands of the small-wares manufacturers have been met by the loom makers with varied types of narrow-ware looms.

Each unit produced on a narrow-ware loom requires its own weaving space, with its individual warp drawn from a beam or from a number of spools in the frame of the loom, its set of harness and reed, and its shuttle or set of shuttles. Simple weaves may require one shuttle, but in fancy weaves with different colored filling yarns as many as six shuttles are used. Plain-woven tapes and articles with twill or sateen weave are woven on cam looms; weaves requiring more shades of harness are produced with dobby heads; while for the fancy weaves Jacquard attachments are required. The variations in the designs of narrow-ware looms are as great as, if not greater than, those of wide fly-shuttle looms.

Yarn preparation.—In the manufacture of the heavier articles, made from unbleached, undyed yarns produced in the plant, the warp yarn is spooled, warped, dressed or slashed, and then sent direct to the loom. When ply warp is used, the single yarn is spooled, doubled, and twisted before being warped. When single filling is used, the filling bobbin goes direct to the shuttle, but when ply filling is required the yarn is doubled and twisted before being quilled.

Warp yarns may be run into skeins, long chains, or spools for the bleaching and dyeing processes. Filling yarns may be bleached or dyed in the skein. Yarns are similarly prepared for mercerizing.

Yarns may be bought in the grey, single or ply, as the case may be, and in skeins, tubes, or long chains, the subsequent processes of bleaching and dyeing being done at the plant. The finest yarns, however, are generally purchased in the bleached or dyed condition, and put through the preparatory processes, as outlined above, at the plant using them. The small-wares plants on narrow wares are generally not equipped for bleaching or dyeing and the yarns are purchased ready bleached or dyed. Some plants at times buy the yarns in the grey and sublet the bleaching and dyeing to outsiders.

The narrow fabric loom.—The early looms, known as tape looms, varied little in type, but the ever-increasing demands of the trade have led to specialization in their construction, and there are now many varieties, differing in design and capacity according to the classes and types of fabrics to be made.

The narrow-ware loom is built on the multiple plan, each loom or machine containing individual weaving units, each of which has its shedding motion, take-up motion, let-off motion, pick motion, and shuttle or shuttles, where more than one color is used in the filling. The question as to the number of units per loom affording the maximum efficiency in production depends in each case upon the type of product. For tapes not over three-fourths inch in width it is assumed that two double-deck looms of 50 divisions each, producing simultaneously 100 tapes per loom, can be tended by one weaver. This, however, would be a maximum task. An objection to looms of so many units is the great loss of production arising from the necessary stoppages. The principle is the same in other multiple types of cotton-manufacturing machines, such as roving and spinning frames. The greater the capacity of the machine the larger is the product, provided the machine is kept continuously running. But it is also true that the greater the capacity of the machine the more frequent are the necessary stoppages and the heavier, therefore, the loss involved. Local conditions, however, determine practice.

In heavy looms, designed for the weaving of heavy tapes, non-elastic webbings, and narrow belts, all closely woven with coarse yarns, a sturdier design is called for, and looms for weaving such fabrics up to 2 inches in width may contain from 12 to 36 spaces each. Still heavier looms, designed for the weaving of ply-fabric belting for machinery and heavy webbings, may contain from 2 to 12 weaving units each.

In narrow-ware looms the shuttles are positively driven, and there are two distinct types of shuttles and drives in use.

For weaving the lighter and narrower fabrics, where floor space is to be economized and where the character of the product will admit of a comparatively large number of units per loom, the looms are frequently designed with the circular shuttle and drive. Figure 1, opposite page, shows the circular-shuttle drive in a standard modern loom. Motion is transmitted to the shuttles by means of a rack-and-pinion combination, the sliding rack in the lay causing fixed pinions to revolve, these in turn meshing with the racks of the shuttles and propelling the shuttles positively always in a direction opposite to that of the sliding rack. In the circular-shuttle type of loom the rack of the shuttle forms an arc of a vertical circle, the arc extending sufficiently each way from the center to insure its constant contact with a pinion, and to admit of the shuttle completely clearing the warp space of the fabric on each stroke. The axis of the body of the shuttle travels in a vertical circular arc, and an equal distance each way horizontally from the center of the weaving space of the unit.

The shuttle, in making its stroke in each direction, follows the arc and climbs upward, and in so doing tends to trespass on the adjoining space, yet through its inclined climb it clears the space without interference, as may be readily seen by referring to Figure 1. The clearance so attained is taken advantage of for building the unit spaces closer together, thus increasing the capacity of the loom per unit of length. Although this type of shuttle drive is adapted to looms for the lighter and narrower fabrics, such as ribbons and tapes, looms for weaving such fabrics are frequently equipped with the straight-shuttle drive. And while for the same number of

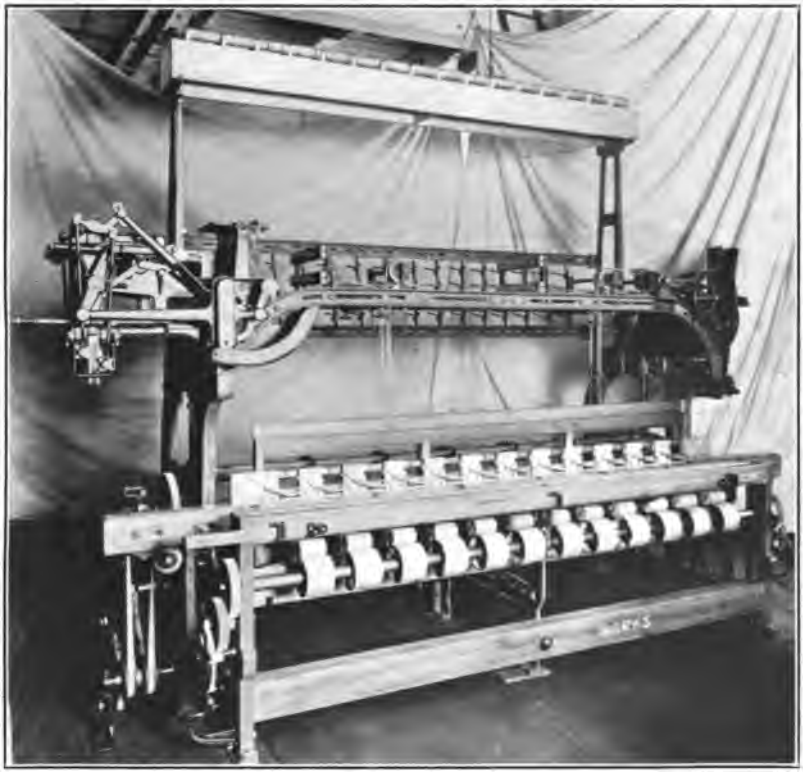

FIG. 1.—RIBBON LOOM. CIRCULAR-SHUTTLE TYPE

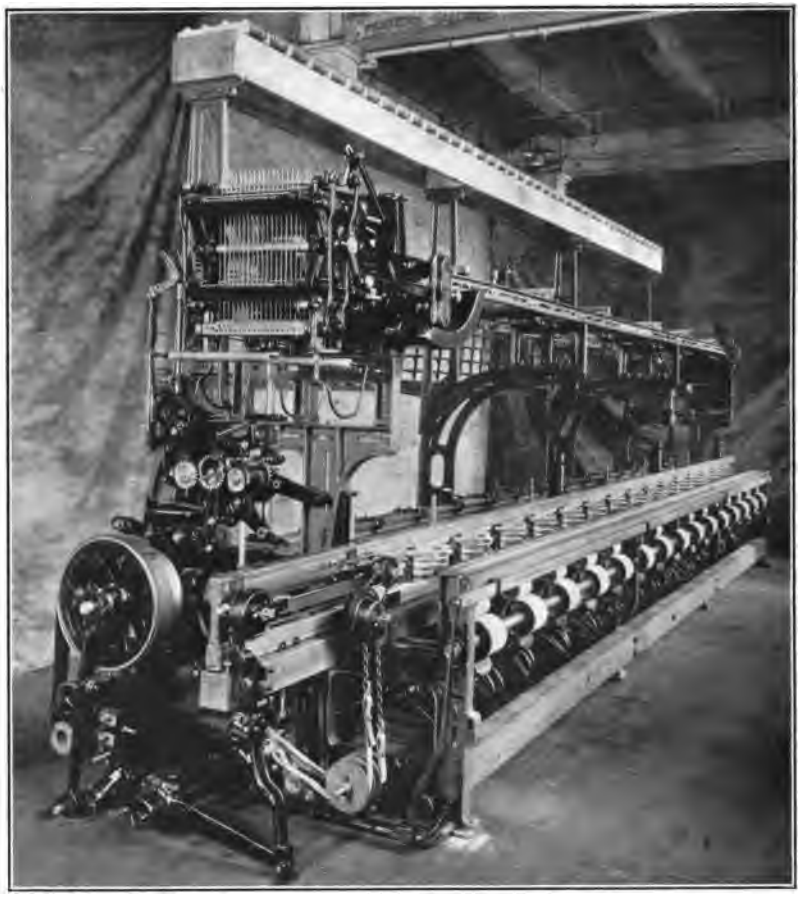

FIG. 2.—RIBBON LOOM. STRAIGHT-SHUTTLE TYPE. FOUR-BANK BATTEN AND SIDE JACQUARD

units per loom the circular shuttle type admits of economy of space, with less length of loom, the straight-shuttle drive admits of higher speed with less wear.

In looms of the straight-shuttle type the shuttle moves on each stroke only in a straight line, parallel with the lay, as may be seen in Figure 2, opposite this page, showing a modern loom equipped with four banks of shuttles. The straight-shuttle type admits of more than one shuttle to the weaving space, some looms being built with as many as six banks, each separate shuttle admitting of a separate color or a different filling yarn. Some looms of this type are built with two decks of shuttles, one above the other, admitting of two separate fabrics being woven in the one weaving space. This plan is sometimes adapted to the weaving of narrow ribbons and tapes; while the capacity of the loom is thus theoretically doubled, it is not to be expected that the product of a double-deck loom will compare in quality with that of a single-deck loom. The straight shuttle is also actuated positively through a rack-and-pinion motion.

Narrow-ware looms are also specially designed for the weaving of elastic webbings, attachments being added for the accommodation and control of the elastic rubber threads or strands woven in with the warp yarns. Garter webbings up to 1½ inches wide are usually woven on looms with 36 weaving spaces. Suspender webbings up to 2½ inches wide are generally woven on looms of 28 spaces. In the case of wider webbings, up to 6 and 8 inches wide, a still smaller number of spaces is used. In the longer looms the lays are frequently built in two equal parts.

Narrow-ware looms are also equipped with dobby heads for weaving fabrics beyond the range of the common cam motions; for weaving labels and other fabrics of extended designs, the looms are supplied with Jacquard heads, the loom being equipped in some cases with the side Jacquard; in other cases two to four Jacquards are placed overhead in the looms. Some looms are equipped with the overshot shuttle and extra warp-shedding device and with fantail or other special types of reeds. Attachments are also added for weaving fabrics with purl edges and tubular selvages, trimmings, conical ribbons, lamp wicks, and buttonholes.

While the bulk of narrow-ware products are produced on multi-space, narrow-ware looms, there is another type of narrow-ware loom which, though a complete weaving unit within itself, weaves or produces only a single end or unit of fabric. High productive efficiency is claimed for this machine on account of its operating speed, as many as 800 to 1,000 picks per minute being stated as practicable. It is also claimed that as many as 24 weaving units of this type can be coupled together on a frame with one drive and tended by one operator. So far this loom has been confined to the weaving of very narrow tapes, not exceeding three-fourths of an inch in width, and it has not been adopted on a commercial scale.

Attempts have been made to construct narrow-ware looms on the vertical plan, having the lay travel vertically, but these have not been introduced commercially.

The parts and attachments of narrow-ware looms vary in size and design according to the use intended. In looms for fine and narrow tapes and ribbons all parts must necessarily be small, and speed is a factor; but in heavy looms, adapted to the weaving of heavy mul-

tiply fabrics in the greater widths, the parts are large and the speed is comparatively low.

Bleaching.—Many narrow wares are made of grey yarns and are not subsequently bleached. The nature of the structure of most narrow wares prevents their successful handling in boiling, washing, bleaching, tentering, or calendering. For this reason, when a bleached finish is demanded by the trade, the article is usually woven of bleached yarns. There are exceptions, however, one being a ply fabric, 4 to 5 inches wide, which, woven with a conical take-up motion, is subsequently bleached and used in the manufacture of semisoft collars.

Cotton may be bleached in the raw and afterwards carded and spun, but stock so treated is affected in its drafting and spinning qualities; while this may not be of much consequence in the manufacture of coarse and medium yarns, yet, for the successful carding and spinning of the finest numbers, nothing can be allowed to reduce the spinning qualities of the material. For this reason bleached cotton narrow wares of the finest weaves are generally produced from yarns spun in the grey and subsequently bleached.

Some plants are equipped for bleaching their yarns in the coarse and medium numbers, but generally purchase their finest yarns in the bleached condition and already gassed.

Cotton yarns are usually bleached by the use of chlorine, the yarn being first boiled off in an alkali solution, then run through a solution of hypochlorite of lime and allowed to set for a certain length of time. It is then thoroughly rinsed and run through water slightly acidulated with sulphuric acid; this is called the "sour" bath. It is again thoroughly rinsed and dried. The nascent chlorine set free from the hypochlorite of lime solution is the active bleaching agent. Yarns can be bleached in skeins, hanks, tubes, cones, in the long chain, or on special spools.

Dyeing.—In the diversification of its products the small-wares trade calls in turn upon the dyeing trade. Owing to the narrow widths and constructions of most small wares very few will admit of piece dyeing and the subsequent processes of finishing necessary in preparing the articles for the trade. For this reason it is customary in the process of weaving to obtain colors by the use of dyed yarns. Many of the coarse and heavy articles are of solid colors.

Direct cotton dyes: In cotton narrow wares, such as the cheaper ribbons and other articles that are not to be washed or laundered, and in which fastness is not of prime importance, the fabrics are in many instances woven from cotton yarns dyed in the grey with direct cotton dyes. Direct cotton-dyed yarns are largely used in the weaving of elastic webbings.

The degree of fastness of dyes of this group varies with the individual dye. On account of their high solubility they have a tendency to run when washed. Many direct dyes are sensitive to acids and fade on exposure to sunlight, while some direct colors are of good fastness, except to chlorine.

In the use of direct dyes the yarn is usually boiled off and thoroughly saturated in a slightly alkaline bath to cut the wax from the fiber of the cotton. The material is then dipped in the hot-dye solution and run or worked until the dye penetration is satisfactory as to uniformity and shade, this sometimes requiring fifteen minutes. The material

is then squeezed or wrung, and is sometime subjected to a cold wash, but in the cheapest work this is not necessary.

Sulphur cotton dyes: In articles where a greater degree of fastness is required sulphur dyes are used. Dyes of this group are used almost entirely on cotton yarns for heavy deep shades, such as blues, greens, browns, and blacks. Sulphur dyes are also used in dyeing artificial silk. As a class, the sulphur dyes possess excellent fastness to washing, acids, alkalis, and, with some exceptions, their fastness to light is good. But as a class they are not fast to chlorine, and do not withstand the repeated treatments of the modern laundry. Sulphur dyes are not pure distinct compounds, and the presence of foreign substances renders them of comparatively low color value.

The sulphur dyestuff is dissolved in sulphite of soda, common salt or Glauber salt is added, and the dye is applied when the solution is at or near the boiling point. The mechanical operation is the same as for the direct dye except that the goods must be thoroughly rinsed after dyeing. Sulphur dyes give heavy, full shades, usually of a less brilliant hue than those produced by the direct and basic dyes. Sulphur dyes are not suitable for cotton yarns used in the weaving of elastic webbings on account of the injurious effect of the sulphur on the rubber strands.

Basic dyes: When shades of special brilliancy are required in the finer articles, such as the better types of ribbons, basic dyes are used. The term "basic" distinguishes these dyes from those of the acid type. They are characterized by their depth, brilliancy of shade, and purity of tone, surpassing all other classes of dyes in such qualities. They possess high tinctorial power, but as a class lack fastness, especially to light and washing, and are used on cotton yarns in dyeing, where bright shades or color tints are desired, without special requirements for fastness. Basic dyes are also used in dyeing typewriter ribbons and to some extent for cotton yarns in the weaving of elastic webbing.

Basic dyes are chemically basic and are fixed on vegetable fibers with acid mordants. The oldest of the coal-tar group, they are not now as important as formerly, owing to their replacement for cotton dyeing by direct dyes and sulphur dyes, both of which have advantages in economy of application and in many cases possess better fastness.

In applying the basic dye the yarn is first run through a solution of tannic acid or sumac. If pure tints are required the yarn is first bleached. The tannic acid is fixed in an insoluble form on the fiber with the aid of tartar emetic or a similar salt. The dyeing operation then takes place by running the yarn into a dye solution at a lower temperature than when using the direct or sulphur dyes. The yarn is worked in slowly, and the work is continued until the desired shade is obtained.

The basic dyes are more expensive than the direct or the sulphur colors—that is, in the dyed goods—partly owing to the extra labor and materials used in the dyeing process.

Vat cotton dyes: The term "vat" originated from the fact that these dyes are applied in a relatively large volume of water at about 120° F. while most other dyes are applied with a small volume of water at a higher temperature. Vat dyes, on account of their high cost, are not commonly used for solid or heavy shades, but rather for

colored stripes, and in dyed yarns for pattern effects. In the weaving of cotton labels for garments and similar articles, yarns dyed with colors of the highest obtainable degree of fastness are required. The variety of dyes for this purpose is limited. Such dyes must be fast to chlorine, washing, alkalis, and perspiration, but not necessarily fast to light. They must not bleed. For such purposes vat dyes and alizarine mordant dyes are almost exclusively used.

Turkey red is of special value and is possibly the fastest red that can be dyed on cotton. For blue the vat blues are used, such as Indanthrene Blue, G. C. D. Vat blacks and combination blacks, such as an indigo bottom with an indanthrene black top, are used for fast blacks. Aniline black is sometimes used, but is not fast to chlorine, being apt to "green-up." For purples, pinks, roses, and yellows, vat dyes are generally used.

Vat dyes, with few exceptions, do not bleed, and thus afford the highest degree of fastness. As they are insoluble in water, they must for dyeing purposes first be reduced to soluble form in an alkaline solution, with the aid of sodium hydrosulphite. The yarn is previously boiled off and rinsed, after which it is run into the solution and worked according to the mechanical process used, then taken out and squeezed or wrung; upon exposure to the air the color is formed by oxidation. The goods are then put through a dilute soap solution, which assists the oxidation, brightens the color, and removes the bath chemicals from the yarn. In dyeing with vat colors the temperature of the vat solution is usually low, but varies with individual colors.

In the domestic industry yarns have been dyed with a fast Turkey red; and alizarine, the base of the dye, has been manufactured in the United States for the past three years. Fast vat yellows, blacks, browns, purples and greens are also manufactured in this country but vat pinks and reds have not yet been produced. The vat colors above mentioned will stand the use required of labels and are preferably used in dyeing yarns for fabrics undergoing laundry treatment. There are domestic cotton shirtings that contain yarns dyed with domestic vat dyes and that withstand laundry treatment.

Mercerized cotton yarns dye as readily as those of raw cotton, and require about 25 per cent less dye material to produce the same shades.

Finishing.—When narrow-wares leave the loom, little remains to be done in the way of finishing processes except sizing, calendering, cutting up, bundling and packing for the trade. Dress or garment trimmings, lingerie ribbons, shoulder strappings, tapes, bindings, dress beltings, and similar articles are calendered when necessary and wound on tubes into rolls. Textile woven belting for machinery is usually wound into rolls without calendering. Certain types are treated by being passed through a hot solution of pine tar, asphalt, or other ingredients, for the purpose of waterproofing and increasing the wearing and pulling qualities. They are then wound into rolls for shipment to the trade. A narrow type of such woven belting is similarly treated, cut into lengths, and sold as brake linings for automobiles. Heavy tapes, like those used for reins, strappings, and heavy webbings, are shipped direct to those manufacturers who use them in their products. Tape spindle banding is shipped in bundles.

Elastic webbings, being woven with rubber elastic strands under tension, tend to pucker unevenly when doffed from the looms. They are run through hot sizing solutions, consisting mainly of thin boiled potato starch, and then dried, under slight tension, in contact with hot cylinders. This process smoothes the fabrics, destroys the uneven internal stresses, and finishes the article with a permanent set. Webbings for the retail trade are rolled, cut to lengths, labeled, and packed.

Ladder tapes are cut and trimmed and rolled to measured lengths.

PRODUCTION AND CONSUMPTION

The inclusive value of the total products of the cotton small-wares industry amounted to $6,394,164 in 1899, $8,016,486 in 1904, $13,174,111 in 1909, $11,525,033 in 1914, $40,896,835 in 1919, and $26,061,193 in 1921.

From the detailed statistics of the domestic production shown in Tables 1 and 1[a], pages 3 and 4, it will be seen that woven narrow wares, or fabrics with fast edges, not exceeding 12 inches in width, were valued at $18,215,958 in 1919; $10,478,302 in 1921; and $45,183,197[1] in 1923.

The domestic consumption of fabrics with fast edges, not exceeding 12 inches in width, is necessarily less than the domestic production, as exports, though relatively small in value, are several times larger than imports.

EXPORTS

Export statistics of fabrics with fast edges, not exceeding 12 inches in width, are not separately recorded, but, as already stated, are much larger in value than imports. Table 5, page 10, shows Canadian statistics for imports from the United States, for the fiscal years ended March 31, from 1911 to 1924, inclusive. The ratio of imports from the United States to total imports from all countries, for each year and for each article, is shown in the percentage column. It will be seen that the ratio of Canadian imports from the United States to the total Canadian imports has exceeded 50 per cent each year. From 1915 to 1919, inclusive, Canada imported all "undyed ribbons for typewriter ribbons" from the United States. In 1920 the proportion so taken was slightly over 99 per cent; in 1924 it dropped to 17.4 per cent. The United States has furnished Canada with a gradually increasing proportion of imports of "belting of cotton," amounting to over 50 per cent in 1918, and while Canada's imports of such belting were not so great in 1921 as in 1918 or 1917, yet their value was much greater in 1921 than in 1920 and 1919; in 1921 the United States furnished about 84 per cent by value, while in 1924 the proportion dropped to 64 per cent. The American share of other Canadian imports has averaged as follows: "Tapes of cotton, not over 1¼ inch in width," 73 per cent in 1919, 47 per cent in 1921, and 48 per cent in 1924; "tape, not dyed or colored," 92 per cent in 1919 and 1921 and 76 per cent in 1924; "webbing, nonelastic, for suspenders," 100 per cent in 1917, 1918, 1919, 1920, 77 per cent in

[1] See page 4 for explanation of incomparability of figures for 1923 with former years.

107634—25†—1-7——3

1921, and 95 per cent in 1924; "tape, dyed or colored," 79 per cent in 1919, 63 per cent in 1921, and 98 per cent in 1924.

It has been stated that the production costs of American and Canadian elastic webbings are about equal, and that exports to Canada are diminishing on account of Canadian classifications by width.

The following table shows Canadian statistics for imports of narrow wares from the United States for the fiscal years ended March 31, 1919 to 1924:

TABLE 10. *Cotton narrow wares—Canadian imports from the United States, 1919–1924*

Classification	Fiscal year				
	1919	1921	1922	1923	1924
Ribbons, undyed, for typewriters	$15,963	$58,395	$14,408	$21,370	$9,400
Belting of cotton	81,921	174,717	56,816	56,122	57,962
Tape of cotton	222,155	168,780	137,815	143,654	132,354
Tape, not dyed or colored	31,350	100,744	59,110	28,354	17,955
Webbing, elastic, over 1 inch wide	298,560	526,127	354,066	333,518	291,988
Webbing, nonelastic, for suspenders	3,316	5,089	7,458	4,344	4,705
Tape, dyed or colored	16,199	20,470	18,718	20,885	23,437
Total	669,464	1,054,322	648,391	608,247	537,801

It will be seen that Canadian imports of narrow wares from the United States amounted in value to over 10 times the American imports for consumption in 1919, as shown, and that in 1921 the ratio was even greater, amounting practically to 14 to 1. It is stated that exports of fabrics with fast edges, not exceeding 12 inches in width, to other foreign countries are relatively small.

Webbings, elastic and nonelastic, are exported to South America, Japan, Australia, Cuba, Porto Rico, China, Norway, and Sweden, but not on a quantity basis.

Some garter webs containing artificial silk are exported to Belgium, France, Italy, England, Switzerland, and the Netherlands, the artificial silk used in these articles being imported from those countries with drawback privileges.

Domestic manufacturers are able to obtain the imported artificial silk at landed prices equal to those quoted for the domestic material. One of the largest domestic firms engaged in the manufacture of the finer grades of narrow fabrics exports some notions to Canada, some elastics to South America, and a line of "middie bands" to Australia, nothing to China or Japan, very little to Europe, and only a few articles in small lots to certain large stores in England. Prior to the World War, another very large and long established company, manufacturing diversified narrow wares, usually exported about 10 per cent of its products, but since the war has been exporting only about 5 per cent, mostly to South America, through various exporting agencies. This firm exports to China, Japan, Egypt, and Canada, but not to Germany.

IMPORTS

Import statistics of fabrics with fast edges not exceeding 12 inches in width were not reported separately prior to July 1, 1918. Imports for consumption are shown in Table 11, from that date to December 31, 1924, inclusive. On the valuation basis, there was a gradual increase up to the enactment of the present law, September 21, 1922. In the latter part of 1922 there was a decided increase. By 1923 the increase had become very marked, imports amounting in value to practically five times the annual average up to September 21, 1922. Preliminary figures for 1924 show a decided decrease compared with 1923 values. Imports consist largely of tapes, typewriter ribbons with fast edges, bandings, skirt beltings, ribbon bands, shoe gorings, elastics, and bindings.

[1] Mainly "Fabrics with fast edges, not exceeding 12 inches in width," this term covers tapes, bandings, beltings, bindings etc. The figures shown also include, without separate record, the following: "And manufactures thereof," under the act of 1922; gimps, galloons, and goring under the acts of 1890 and 1894; garters, suspenders, braces, cords, tassels, cords and tassels, and tire fabrics, prior to July 1, 1918; and tubings (including bone casings) prior to the act of 1922.

[2] For 1891 there were "cords, braids, gimps," etc., not included, to the value of $184,033; duty, $64,412 rate, 35 per cent, coming in under the act of 1883.

[3] July 1 to Aug. 27, 1894, inclusive.

[4] Aug. 28, 1894, to June 30, 1895, inclusive.

[5] July 1 to Oct. 3, 1913, inclusive.

[6] Oct. 4, 1913, to June 30, 1914, inclusive.

[7] July 1 to Dec. 31, 1918, inclusive.

[8] Plus 7 cents a pound if containing cotton having staple of 1⅛ inches or more under emergency tariff act of May 27, 1921.

[9] Includes imports valued at $309,638, dutiable at 25 per cent ad valorem and 29,684 pounds, valued at $54,896, dutiable at 25 per cent ad valorem and 7 cents a pound.

[10] Jan. 1 to Sept. 21, 1922, inclusive.

[11] Includes imports valued at $251,985, dutiable at 25 per cent ad valorem, and 19,557 pounds, valued at $54,416, dutiable at 25 per cent ad valorem and 7 cents per pound.

[12] For 11,673 days, equivalent to 32 years.

[13] Sept. 22 to Dec. 31, inclusive.

[14] Classifications under the act of 1922; fabrics with fast edges not exceeding 12 inches in width, and articles made therefrom; tubings; cords, tassels, and cords and tassels; garters, suspenders, and braces.

[15] Preliminary figures.

COMPETITIVE CONDITIONS

Detailed statistics are not available, but it is stated in the trade that competitive imports are mainly from Germany, with occasional shipments from England, France, Switzerland, and other countries. Germany has long been the chief source of imports of woven and braided narrow wares, the industry being well established and highly developed in Barmen, Crefeld, and Elberfeld. While both German and American manufacturers import their finest cotton yarns from England, the Germans have the advantage in the import duties which domestic manufacturers are compelled to pay on this raw material. German manufacturers have the further advantage of cheaper dyes, and where absolutely fast and satisfactory dyes of the highest quality are required they enjoy a decided advantage in competing for orders. These phases of competitive conditions are discussed in greater detail in Section IX—Labels for garments and other articles.

A special narrow-woven fabric, from 7 to 8 inches in width, known as baby binding, is imported from Italy for use among the population of Italian extraction. It is said that no comparable article is produced in the domestic industry. Imports of typewriter ribbons with fast edges are due largely to the fact that domestic typewriter ribbons are made from strips cut from wide-woven fabrics, and consequently without fast edges.

The technical skill and knowledge of the domestic manufacturer are fully equal to that of the foreign producer, but in the matter of labor and material costs the foreign manufacturer has the advantage. In order to reduce costs, the domestic manufacturer strives for quantity production, but the foreign manufacturer, with the advantage of cheaper and more abundant labor, is able to compete successfully for small orders. In the line of elastic fabrics and webbings the domestic industry is firmly established, competitive imports consisting mostly of shoe gorings from Germany and small elastic webs of a staple, plain type from England, produced and handled on a quantity basis.

TARIFF HISTORY

The inclusive term "Fabrics with fast edges not exceeding 12 inches in width" (embracing articles made of cotton or of which cotton is the component material of chief value, or of cotton and india rubber, and not embroidered by hand or machinery) was first employed in the act of 1913, which imposed a duty of 25 per cent ad valorem on imports. In the act of 1922, "Fabrics with fast edges not exceeding 12 inches in width, and articles made therefrom," is the inclusive term used, and imports of such articles, composed wholly or in chief value of cotton, or of cotton and india rubber, are subject to a duty of 35 per cent ad valorem.

FOREIGN PRODUCTION

Statistics of production in foreign countries are not available.

COURT AND TREASURY DECISIONS

Under the acts of 1883 and 1890 elastic webbing composed of cotton and india rubber was held to be dutiable as webbing. (G. A. 133, T. D. 10483 of 1890; G. A. 1223, T. D. 12539 of 1892; G. A. 2150, T. D. 14151 of 1893; G. A. 2449, T. D. 14727 of 1894; G. A. 3812, T. D. 17937 of 1897.)

Under the act of 1894 cotton beltings which were not specifically provided for were held to be dutiable as manufactures of cotton at 35 per cent ad valorem. (G. A. 3944, T. D. 18234 of 1897.)

Under the act of 1897 so called bridle tapes of cotton, braided on a braiding machine, about three-sixteenths of an inch wide, and intended to be used as a part of piano-forte actions, were held to be dutiable as cotton tapes under paragraph 320 and not as cotton braids. (G. A. 5650, T. D. 25216 of 1904.)

Tapes and ladder tapes are not the same thing, and an importation of ladder tapes, not shown to be within the commercial designation of tapes, was held to be dutiable as a manufacture of cotton under the act of 1909. (*United States* v. *Walter*, 3 Ct. Cust. Appeals, 94 of 1913.)

Under the act of 1913 the following decisions were rendered: Cotton bandages in the piece in their entirety, not commercially suitable for any other use than to be cut into bandages, were held to be dutiable as bandings under paragraph 262, and not as cotton cloth under paragraph 252. (G. A. 8237, T. D. 37933 of 1919; T. D. 35952 of 1915.)

Narrow-woven articles less than 1 inch in width with a finished pattern or design along one edge, cotton chief value, were held to be dutiable as bindings. (Abstract 37682 of 1915; *Massce* v. *United States*, 3 Ct. Cust. Appeals, 470 of 1912.)

Strips of cotton cloth approximately 4 inches wide and from 5 to 6 yards in length were held to be dutiable as bandings. (T. D. 34284 of 1914.)

Elastic webbing in chief value of cotton was held to be dutiable as cloth fabric with fast edges not exceeding 12 inches in width. (Abstract of 37644 of 1915.)

The *eo nomine* provision for belts in paragraph 262 was held to be more specific than the provision for wearing apparel in paragraph 256, and belts composed of silk and cotton were held to be dutiable under paragraph 262. (Abstract 46277 of 1923.)

Cotton tapes not being especially provided for were held to be dutiable as fabrics with fast edges not exceeding 12 inches in width under paragraph 263, rather than under paragraph 358. (Abstract 44681 of 1922.)

Woven cotton fabrics in the piece, not exceeding 12 inches in width, with fast edges and with printed designs at regular intervals, were held to be more specifically provided for in paragraph 262 as fabrics with fast edges not exceeding 12 inches in width than as printed cotton cloth in paragraph 252. (G. A. 8327, T. D. 38316 of 1920.)

Coarse cotton fabric from 7 to 9 inches in width, having looped edges, shown to be used in connection with lace or other trimmings for making bedspreads, in such fashion that the lace or other trimming was attached to the looped edge of the fabric, was held to be dutiable as "Fabrics with fast edges not exceeding 12 inches in width" under paragraph 262, rather than as "trimmings" under paragraph 358. (Abstract 42501, of 1918.)

II. TUBINGS

General Information

DESCRIPTION AND USES

Tubings of cotton, covered by paragraph 913 of the act of 1922, include mostly small wares produced on narrow-ware looms. Tubings are woven with two distinct warps, upper and lower, the weave being complete on four picks, producing a double fabric connected at the edges. This is the principle used in the weaving of seamless bags and pillow tubings on wide looms. Tubings serve as bone casings for enclosing corset steels, for the incasing of the stems of artificial flowers and for other purposes. Some are produced on braiding machines and used as "sleevings" for insulating purposes in the electrical industry.

Various types of lamp and stove wickings are also tubular woven on narrow-ware looms, and some are also tubular braided, but such wickings are specifically mentioned in paragraph 913 and provided for at a special rate of duty. Certain types of fire hose, also tubular woven, are provided for under paragraph 1007 as "Hose suitable for conducting liquids or gases, composed wholly or in chief value of vegetable fiber." Pillow tubings and seamless bag fabric are dutiable as countable cotton cloth.

DOMESTIC PRODUCTION

Tubings constitute a small and relatively unimportant portion of the domestic production of cotton small wares, and are not separately recorded in the census statistics. The textile directories do not show any plant engaged exclusively in the manufacture of tubings, and there is no record of exports in published official statistics.

IMPORTS

Under previous tariff acts, imports of tubings have not been recorded separately from other cotton small wares, but are reported to have been negligible. In the statistical classification of imports effective September 22, 1922, a separate import number was assigned to tubings of cotton, but up to December 31, 1922, inclusive, there were no imports classed under this heading. In the calendar year 1923 imports of tubings amounted to 237 pounds, valued at $234; duty collected $82. Preliminary figures for 1924 show imports of 208 pounds, valued at $396, duty collected $139.

Tubings, under consideration, constitute a very small portion of the output of the domestic small-wares industry, and at present meet with little competition from abroad.

TARIFF HISTORY

Tubings were not mentioned in the acts of 1883, 1890, or 1894. The act of 1897 provided for tubing, also bone casings "made of cotton or other vegetable fiber," at the rate of 45 per cent ad valorem. The act of 1909 provided for tubings and bone casings, "made of

cotton or other vegetable fiber, and india rubber, or of which cotton or other vegetable fiber is the component material of chief value," at the rate of 45 per cent ad valorem. Tubings were not specifically mentioned in the act of 1913, but bone casings, "made of cotton or other vegetable fiber, or of which cotton or other vegetable fiber is the component material of chief value, or of cotton or other vegetable fiber and india rubber," were provided for at 25 per cent ad valorem. The act of 1922 provides for tubings, "composed wholly or in chief value of cotton or of cotton and india rubber, and not specially provided for," at 35 per cent ad valorem, but omits specific mention of bone casings, on the ground that they are a variety of tubing. Tubings are specially mentioned in this act, since, being tubular-woven and therefore without selvages, they might be held as not included under "fabrics with fast edges not exceeding 12 inches in width."

Court and Treasury Decisions

Cotton bone casings, not commercially known as galloons, were held to be dutiable as manufactures of cotton under paragraph 264 rather than as galloons under paragraph 263. (G. A. 3026, T. D. 16002 of 1895.)

III. GARTERS, SUSPENDERS, AND BRACES

General Information

DESCRIPTION AND USES

A garter may be defined as a band worn around the leg to hold the stocking in place; loosely, any stocking supporter. Garters worn by men are generally made to encircle the leg, the ends fastening together with clasps, and provided with catches to grip the sock. Garters worn by women and children may be of the type that encircles the leg, or they may be made as hose supporters. Garters may also be worn as arm bands.

A suspender is one of a pair of straps passing over the shoulders to support the trousers or one of a pair of braces.

Garters and suspenders generally have elastic webbing as their basic material; in some types nonelastic webbing is substituted, in others there is a combination of the two.

The English use the term "braces" instead of suspenders, and the most popular suspenders imported from France are labelled "bretelles." In the domestic industry the term "braces" is sometimes synonymous with the word "suspenders," but is more often confined to body braces, made of elastic or nonelastic webbings, worn to correct round shoulders or other physical defects.

THE DOMESTIC INDUSTRY

History.—The garter and suspender industry is the largest consumer of the output of the domestic elastic-webbing industry, and the two industries are so interdependent that their history is practically one.

The manufacture of elastic webbing dates back to about 1840 in Europe, but did not begin in this country until about 1860. The earliest uses of elastic webbings were for the manufacture of shoe gorings, garters, and suspenders, special types being produced for each purpose. Garters and suspenders made of elastic webbings supplied a long-felt want, and rapidly superseded the makeshifts previously employed. The manufacture of these articles has steadily developed into an industry with an annual output of millions of dollars in value.

Geographical distribution.—Details as to the development of the manufacture of "suspenders, garters, and elastic woven goods" in the United States and in the various States in the census years 1909, 1914, 1919, and 1921 are recorded in Table 13, below. Prior to 1909 elastic woven goods were included in part under men's furnishings, in part under millinery and lace goods, and in part under rubber and elastic goods (now classified as "rubber tires, tubes, and rubber goods not elsewhere specified"). In addition to the products covered by the table, suspenders, garters, and elastic woven goods to the value of $694,035 in 1914 and $2,017,142 in 1919 were reported under other classifications.

Of the establishments recorded by the census as engaged in the manufacture of suspenders, garters, and elastic woven goods in 1921, 55 were in New York; 27 in Massachusetts; 17 in Connecticut. In

1921 the total number of establishments was 170, as compared with 251 in 1909. Statistics for 1923 show 99 establishments producing suspenders, garters, and elastic woven goods, from purchased webbing, as follows: New York, 44; Illinois, 12; Massachusetts, 11; Connecticut, 6; Ohio, Pennsylvania, and Wisconsin, 4 each; Minnesota and Missouri, 3 each; the remaining 8 were in Colorado, Iowa, Louisiana, Michigan, New Jersey, and North Carolina.

[1] Includes principal materials, fuel, and rent of power.
[2] Includes 21 establishments with products less than $5,000 each.
[3] Figures not available.
[4] Figures for subdivision by States not available for the years 1921 and 1923.
[5] Included in "All other."

Organization and equipment.—Owing to changes in classification, the figures for the census years shown in the table below are not directly comparable because of the fact that the 1923 data are limited to plants that purchased the webbing from which they manufactured suspenders, garters, and other elastic woven goods. While in earlier years it was the usual practice for manufacturers to buy their materials, some plants produced their own fabrics, a few turning out a full line of elastic and nonelastic webbings, as well as the braided cords used in garters and suspenders of certain types.

The equipment of plants engaged in this line of manufacture is largely confined to machinery for cutting, stamping, and sewing. Buttonholes in the webbings are usually made in the weaving process.

TABLE 14.—*Suspenders, garters, and elastic-woven goods—Organization and equipment, census years 1909–1923*

[Source: Federal Census]

	1909	1914	1919 [1]	1921 [1]	1923 [2]

Salaried employees	1,153	1,193	1,430	1,198	----------
Wage earners, average number	10,141	9,646	10,857	9,493	3,457
Primary horsepower	4,899	7,524	(3)	(3)	824
Capital	$15,207,880	$16,343,686	$39,676,879	(3)	----------
Salaries and wages	5,818,977	5,931,600	12,861,000	$11,436,000	----------
Salaries	1,545,675	1,655,474	3,591,000	2,647,000	----------
Wages	4,273,302	4,276,126	9,270,000	8,789,000	$2,871,526
Paid for contract work	(3)	236,543	470,000	569,000	----------
Materials, fuel, rent of power	(3)	15,191,194	36,369,000	27,233,000	13,934,072
Value of products	(3)	24,432,753	60,775,000	44,935,000	24,297,342
Value added by manufacture	(3)	9,241,559	24,406,000	17,702,000	10,363,270

[1] Establishments with products valued at less than $5,000 are not included in the figures for 1921. There were 12 of this class, reporting 5 wage earners, with products valued at $31,000. For 1919, however, figures for 21 establishments of this class, reporting 21 wage earners, and products valued at $56,000; and for 1914, 30 such establishments, with 15 wage earners, and products to the value of $62,000, are included in all items with the exception of "Number of establishments."

[2] Figures are not comparable with those for previous census years. For explanation of apparent decrease see text above.

[3] Figures are not available.

Materials used.—The principal material used in the manufacture of garters, suspenders, and braces is elastic webbing, but nonelastic webbing, elastic and nonelastic braided cords, ribbons, metal buckles, catches, fasteners, and cloth, as well as leather, are also employed.

The webbings are woven on narrow-ware looms, and are mainly of cotton yarns, which may be in whole or in part grey, bleached, mercerized, or dyed. Braided fabrics are also produced from similar yarns. In the elastic woven webbings, elastic threads of india rubber are woven in with the warp, and are used in the cores of the elastic braided cords. With rare exceptions, the materials used are of domestic manufacture. In addition to these articles covered by paragraph 913, the industry utilizes similar articles, but of materials provided for in other textile schedules of the present law.

The domestic manufacture of garters, suspenders, and braces is so dependent upon that of the elastic webbings entering into them that an outline of the development of the elastic webbing industry may be of interest at this point.

The weaving of rubber elastic threads with other materials began about 1840. The American industry was started about 1860, although for a number of years previously England, Germany, and France in a small way had found in this country a market for their products, particularly in cords, braids, and shoegorings. A few looms were brought over from England and installed at Easthampton, Mass., and the manufacture of shoegoring was begun.

For some time the rubber thread required was imported from England. The business grew rapidly, and factories were installed in Boston, Lowell, and Brockton, Mass.; in Bridgeport, Conn.; and in Camden, N. J. A labor dispute about 1890 ultimately caused the shoe trade to abandon the use of goring web and most of the looms making such webbing were diverted to the manufacture of other types of elastic webbings.

Attempts have been made to weave elastic webbings on wide looms, the cloth being divided at intervals, according to the widths required,

by gaps in the warp, binder threads being woven in at each edge. The strips were cut apart by knives properly placed in the loom. While this method was much more economical than weaving individual webs in gang or narrow-ware looms, the product was unsatisfactory, owing to the lack of finish and the imperfect edges.

Attempts were also made to calender an elastic substance between two separate, finely woven cloths, afterwards cutting the product into narrow strips of the desired widths. This method was simple, and though admitting of the use of a great variety in outer cloths, some of which were finished by embossing and printing, it was also discarded by the trade. The webbing business ultimately settled down to the weaving of narrow-ware elastic goods, plain and fancy, on narrow-ware or gang looms, and the business has steadily grown along those lines. Some narrow-ware looms for the weaving of webbings used in suspenders and braces and in certain types of garters are equipped with attachments for producing the necessary buttonholes in the process of weaving.

In the weaving of elastic webbings the proper manipulation of the rubber warp threads and the yarns calls for skill and extensive experience. Atmospheric conditions also affect the product, especially in weaving, widening the phases of the problems. A low humidity being necessary in weaving elastic webbings, it is sometimes necessary to use artificial heat in warm weather in order to lower the relative humidity in the weaving rooms.

In making some braided elastic webbings, intended for arm bands and garters of certain types, the elastic rubber strands are first put through a braiding machine; this produces an elastic "soutache" braid, the rubber being completely covered with the braiding threads. This elastic "soutache" braid is woven into the finished fabric in the final process.

During the World War special requirements for certain kinds of elastic webbings made it necessary that the elastic rubber strands be completely covered with yarn or thread before being woven into the webbing. The object of this was to increase the life of the elastic threads in service by protecting them against the effects of perspiration and humidity. It was said that the life of the fabric was practically doubled by this expedient. For the same reasons surgical bandage elastic webs, which are required to be soft and in which the texture varies by reason of the different widths called for by the design, are made with rubber strands previously covered with braiding.

The yarns used vary in fineness and ply, and the webs and cords, being subject to changing fashion, vary greatly in design, size, and texture. An important part of all elastic webs consists of the elastic rubber threads used in the warp, as is the case also in the braiding of elastic cords. The yarns used in domestic elastic fabrics are of domestic manufacture, being within the range readily furnished by domestic spinners. The rubber elastic threads are also purchased in the domestic market.

The preliminary processes preparatory to weaving are similar to those employed in the production of other narrow wares, the rubber strands calling for special treatment and handling.

In weaving elastic webbings the simplest method is that used in making garter webs and similar fabrics used in the household. These are generally made on plain cam ribbon looms, some types of which

are capable of producing as many as 56 pieces or strips at one time. The more common webbings are loom webs, lisles, and cables, all of which are of single-cloth construction. The filling threads constitute the most conspicuous features, and the fabrics range in width from one-fourth inch to 2 inches. Two cotton warps are usually employed: One of these, the binder, weaves two up and two down, while the other, called the gut or filler warp, weaves with the rubber warp, one up and one down. The selvage is formed by the filling pick passing around the stationary steel wire fastened in the loom at the edge of the warp. The end of this wire, over which the pick of filling passes, tapers to a point and, being stationary, the picks slide from it as the web is carried forward in the process of weaving. Looms of both the straight shuttle and the circular shuttle type are used.

Lisle webs are also plain, but are made with high-grade, combed, gassed yarns for the filling, and are woven with four binder warp threads between the strands of rubber instead of two as in the loom web. In the weaving, the filling commonly used consists of a 26s two-ply combed gassed yarn.

All bleaching and dyeing must necessarily be done in the yarns before weaving, as the webbing can not be subjected to any boiling processes. As explained in the chapter on small wares, sulphur dyes are not suitable for yarns to be used in elastic webs on account of the effect of the sulphur on the rubber.

The cable web is the most popular type for use in men's garters. It shows the prominence of the two dent ribs and differs in appearance from the plain web.

The French web, or railroad weave, an intermediate grade between the loom and the lisle web, is also used.

The principal use of elastic webbings is for suspenders, garters, and braces, which articles call also for nonelastic webbings. Innumerable other uses are found for what are commonly known in the trade as "elastics."

Elastic webbings, after leaving the loom, are slashed with sizing materials containing starch, and calendered over steam-heated cylinders, under sufficient tension to finish the fabric with a smooth surface acceptable to the trade. The webbings in this condition go to the manufacturers of garters, suspenders, and braces, who depend entirely upon the domestic supply of these materials.

Methods of production.—The manufacture of garters, suspenders, and braces from elastic and nonelastic webbings consists practically of cutting up, stamping, sewing, stitching and binding, and the affixing of buckles, clasps, fasteners, and catches, the articles being then assorted and packed for shipment. Shirred ribbon garter stock is also prepared by enclosing braided elastic fabrics, under tension, between fancy shirred ribbons, in the process of stitching on sewing machines. Fancy garters and supporters are made from such stock in many varieties and styles, the subsequent process consisting mainly of cutting and stitching, and the addition of decorative articles. Garter materials are also sold in the retail trade, and many articles are made in the homes of the ultimate consumers.

Production and consumption.—The production of suspenders, garters, and elastic-woven goods was valued in 1923 at $24,297,342; in 1921, at $44,935,467; in 1919, at $60,774,652; and in 1914, at $24,432,753. The value of suspenders and garters is not recorded

separately from other elastic woven goods, and there are no statistics as to quantity.

The import classification groups "garters, suspenders, and braces," while export figures are for "suspenders and garters," and production statistics for "suspenders, garters, and elastic-woven goods." Owing to these variations in classification and to figures not being separately shown for any one article, no strict comparison of domestic production, imports for consumption, and exports can be made. Figures for the last three census years are as follows:

	1919	1921	1923
Domestic production of "suspenders, garters, and elastic-woven goods"	$60,774,652	$44,935,467	[1] $24,297,342
Imports for consumption of "garters, suspenders, and braces"	22,364	136,776	62,075
Exports of "suspenders and garters"	2,551,858	751,676	970,547

[1] Not comparable with 1921. See p. 34 for explanation of apparent decrease in figures.

It will be evident from the above table that domestic consumption practically depends upon domestic production.

EXPORTS

The value of exports of suspenders and garters for the years 1918 to 1923 is shown in the following table:

TABLE 15.—*Suspenders and garters—Exports 1918–1923*

	1918	1919	1920	1921	1922	1923
Total countries	69	85	83	73	67	87
Total exports, value	$1,185,985	$2,551,858	$4,143,487	$751,676	$720,690	$970,547
Canada	76,000	139,000	157,000	136,000	74,944	70,616
Mexico	43,000	81,000	178,000	98,000	45,830	95,334
Cuba	119,000	244,000	418,000	76,000	115,914	156,049
Argentina	168,000	383,000	772,000	69,000	204,793	247,134
Australia	103,000	97,000	162,000	45,000	16,883	22,774
Japan	27,000	44,000	41,000	33,000	25,996	15,947
England	55,000	121,000	193,000	31,000	9,131	11,864
Denmark	22,000	286,000	65,000	24,000	8,817	8,298
Brazil	66,000	88,000	384,000	19,000	2,302	5,486
New Zealand	17,000	45,000	109,000	14,000	35,382	83,128
Germany		147			500	
All other countries	489,985	1,023,711	1,664,487	206,676	180,198	253,917

It may be noted that while suspenders and garters were exported in appreciable quantities to many countries during the five years shown, practically none went to Germany.

Canadian statistics of imports from the United States of "braces, suspenders, and finished parts of"; "webbing, elastic, over 1 inch wide"; and "webbing, nonelastic, for suspenders," for the fiscal years ended March 31, 1919 to 1924, inclusive, will be found in Table 5, page 10.

IMPORTS

Garters, suspenders, and braces were not separately recorded in imports for consumption prior to July 1, 1918. Table 16 shows imports from that date to December 31, 1924, inclusive. Imports of suspenders have for many years consisted almost entirely of a well-known brand, made in Paris. These are well made and practically all hand-sewed, tending to increase the life of the article in

use. The name of the maker appears on each pair. They are nonelastic, but have elastic backs and fabric tabs or thumb pieces on each buckle.

TABLE 16.—*Garters, suspenders, and braces, of cotton*[1]*—Imports for consumption—Revenue, 1918–1924*

Calendar year	Rate of duty	Quantity	Value	Duty collected	Unit value	Actual and computed ad valorem rate
		Number				*Per cent*
1918 [2]	25 per cent ad valorem	102,649	$15,076	$3,769	$0.1469	25.00
1919	do	66,580	22,364	5,591	.3359	25.00
1920	do	108,159	31,945	7,986	.2954	25.00
1921	do. [3]	[5] 422,530	[5] 136,776	34,423	.3237	25.17
1922 [4]	do. [3]	[6] 279,104	[6] 103,901	26,109	.3723	25.13
1922 [7]	35 per cent ad valorem	24,318	8,639	3,023	.3553	35.00
1923	do	251,023	62,075	21,726	.2472	35.00
1924 [8]	do	245,237	61,649	21,577	.2514	35.00

[1] Not recorded separately prior to July 1, 1918.
[2] From July 1 to Dec. 31, 1918, inclusive.
[3] Plus 7 cents a pound on those containing cotton having a staple of 1⅛ inches or more, under emergency tariff act of May 27, 1921.
[4] From Jan. 1 to Sept. 21, 1922, inclusive.
[5] Includes 399,330 (weight not stated), valued at $127,800, dutiable at 25 per cent ad valorem, and 23,200 (weighing 3,278 pounds), valued at $8,976, dutiable at 25 per cent ad valorem and 7 cents a pound.
[6] Includes 264,222 (weight not stated), valued at $98,492, dutiable at 25 per cent ad valorem, and 14,882 (weighing 1,911 pounds), valued at $5,409, dutiable at 25 per cent ad valorem and 7 cents a pound.
[7] From Sept. 22, to Dec. 31, inclusive.
[8] Preliminary figures.

One large domestic manufacturer states that this special French brand is practically the only type imported, and that it is doubtful if the total imports of suspenders aside from this brand amount to $10,000 per year.

COMPETITIVE CONDITIONS

The domestic industry is firmly established and controls the domestic market. Imports of garters, suspenders, and braces constitute, in value, less than 1 per cent of the domestic production, and generally consist of specialties of long established reputation, demanded by certain domestic consumers even at prices greatly in excess of those of comparable domestic products.

TARIFF HISTORY

Suspenders and braces were first mentioned in the act of 1883 and garters in the act of 1897. In the act of 1883 the provision was for suspenders and braces of cotton; and in the act of 1890 for suspenders and braces, elastic or nonelastic, of cotton; in the act of 1894, for suspenders and braces, of cotton or other vegetable fiber, and whether composed in part of india rubber or otherwise. The acts of 1897, 1909, and 1913, although differing slightly in their phrasing, provided for garters, suspenders, and braces, made of cotton or other vegetable fiber, either with or without india rubber. The act of 1922, paragraph 913, provides for "garters, suspenders, and braces, composed wholly or in chief value of cotton, or of cotton and india rubber, and not specially provided for, 35 per centum ad valorem." Similar articles made in chief value of other textile materials are provided for under other textile schedules.

The exact texts of the tariff provisions from 1883 to 1922, inclusive, are shown on page 14.

UNIVERSITY OF MICHIGAN LIBRARIES

FOREIGN PRODUCTION

No information is available as to foreign production.

PRICE DATA

Garters, suspenders, and braces are made in so many different styles, of such varied materials, sizes, details, etc., that no staple prices can be quoted. Each manufacturer is likely to have his individual line of styles and constructions, which in turn may follow to some extent, the changing fashion.

One large domestic manufacturer, who also imports the well-known French suspenders previously referred to, states in regard to these:

> The invoice price according to the last shipment made from Paris, March 29, 1923, was $5.25 per dozen pairs, landed at New York, including the duty of 35 per cent, and these are in turn wholesaled at about $7 per dozen, and retailed at anywhere from 89 cents to $1 per pair.
>
> As far as competition with merchandise of a similar character made in this country is concerned, the genuine French suspenders sell at about 75 per cent higher, as goods made in this country sell at about $4.25 per dozen pairs, and retail at about 50 cents per pair.

A very large firm of wholesalers, jobbers, and importers stated the landed price of this same brand, about the middle of February, 1923, as $6.03 per dozen pairs for regular lengths, selling at $6.90 per dozen pairs; and $6.63 per dozen for extra lengths, selling at $7.50 per dozen pairs.

Prices in small wares vary according to demand and competition, as is the case with staple articles, and in the line consisting largely of novelties, the novelty and the temporary demand will largely govern in the matter of price for the time being.

WAGE DATA

Table 14, page 35, shows the total average number of wage earners and the total wages paid for the years 1909, 1914, 1919, 1921, and 1923, in the industry known as "suspenders, garters, and elastic woven goods." According to these data, the average annual wages amounted to $443 in 1914, $853 in 1919, $926 in 1921, and $830 in 1923. However, these figures can not represent, relatively, the absolute average wage per operative per hour during the four years taken. In practically all industries wages were higher in 1919 than in 1921, and much higher than in 1914. Again, since the labor turnover reached its peak in 1919, owing to the market being controlled by the sellers of both merchandise and labor, it is evident that a comparison based upon the average number of wage earners appearing on a weekly or monthly pay roll affords no clear idea of the scale of wages paid. Again, the inclusion of "elastic woven goods" may mean that the figures represent many lines of articles distinct from "garters, suspenders, and braces."

Information concerning foreign wages, hours, and working conditions is not available.

COURT AND TREASURY DECISIONS

There are no decisions of importance on these articles made with cotton the component material of chief value.

IV. CORDS, TASSELS, AND CORDS AND TASSELS

General Information

DESCRIPTION AND USES

A cord may be formed by braiding, by doubling or plying, or by twisting or cabling two, three, or more strands or threads or yarns together. Cords may be larger or smaller than twine, but are generally assumed to be smaller than rope. However, neither the industry nor the trade agrees upon the precise definitions of the terms of "twine," "cord," or "rope."

Cords are manufactured of various materials, either alone or in combination with tassels or other pendant ornaments to match. They are used in upholstery, for window shades, curtains and draperies; in the clothing and garment trade, for uniforms, hats, caps, regalia, bath robes, blouses, shirts, etc.; and in the millinery trade. They may be supplied by the trade in notions and novelties for trimmings, for attaching to hand bags, purses, vanity cases, etc.

One type, known as coronation cord, is made by the compound plying and twisting of different strands or threads, the component ends being delivered at different rates in the process of twisting, so that the strand forming the surface appears completely wrapped around the inner ends of the material. The variation in the rate of delivery in the final forming of the cord has the further effect of causing the diameter of the finished article to vary throughout its length, thus lending a novel appearance to the article. Coronation cords are generally used for trimming and decorating purposes, being sewed on in various designs.

Braided cords may be either elastic or nonelastic, and may vary in size from the small tubular braided cord with a single rubber thread, such as is used for securing eye glasses, up to a cord in which the braided rubber strands and threads are of sufficient size and strength for gymnasium apparatus.

Still larger elastic cords are used in the shock-absorbing mechanism of airplanes.

Tassels are pendant ornaments for use in connection with cords. A tassel generally consists of a tuft or bunch of loosely hanging threads, strands, or cords, of one length, gathered at the upper end or in the middle, and made fast and finished by means of a button or mold. It may be attached to the cord, forming the combination of a cord and tassel. In some tassels the strands of material simply pass through the hole in the mold and, dropping over on the outside, are gathered and bound just below the mold. In more elaborate types, the tuft of strands terminate within the mold, which is sometimes covered with material harmonizing with the strands. In addition to "cords" and "tassels," which are separately mentioned, the tariff

UNIVERSITY OF MICHIGAN LIBRARIES

acts of 1913 and 1922 also specifically mention "cords and tassels," this having been made necessary by reason of a judicial decision to the effect that the combination consisting of a tassel attached to a cord is covered neither by the term "cord" nor by the term "tassel."

THE DOMESTIC INDUSTRY

The manufacture of cords and tassels, a comparatively simple process of manipulating materials, constitutes a minor branch of the small-wares industry. There is no official record as to the size of the industry, its geographical distribution, or the value of the annual output. Cotton cords are produced in cordage plants along with rope and twine, in cotton spinning mills, and in braiding plants. Both cords and tassels are also produced by specialty manufacturers who cater to the upholstery, garment manufacturing, and dress goods trades. They are also made by the manufacturers of the articles requiring their use.

One of the oldest and largest domestic companies, engaged in the manufacture of uniforms, regalia paraphernalia, trimmings, etc., established over 100 years, manufactures full lines of cords, both braided and plied, of cotton, mercerized cotton, silk, and mohair, bleached and dyed, and metal tinsel threads. With the exception of the metal tinsel threads, imported from France, all materials are of domestic manufacture. The company also manufactures full lines of tassels, as well as acorns and other pendants, matching the cords as to materials and designs. It produces a full line of three-ply twisted cords, with tassels to match, of red, white and blue yarns, for military uniforms. During the war it furnished the Government with braided cotton cords for the uniforms of enlisted men, but since the war the same articles are being made of mohair. The company imports from France a supplementary line of cords, made of twisted metal threads or strands, braided on cotton cores, as well as tassels to match.

Another large domestic manufacturer, established over a third of a century, makes a full line of cords and tassels for the upholstery trade, using both bleached and dyed yarns of cotton, mercerized cotton, silk, etc., all of domestic manufacture, but imports the tinsel materials from France. This firm imports no finished products.

EXPORTS

Exports of cords and tassels are not separately recorded.

IMPORTS

Prior to July 1, 1918, imports of cords and tassels were not recorded separately from those of other cotton small wares. The following table shows imports since that date.

TABLE 17.—*Cords, tassels, and cords and tassels, of cotton* [1]*—Imports for consumption—Revenue, 1918–1924*

Calendar year	Rate of duty	Quantity	Value	Duty collected	Unit value	Actual and computed ad valorem rate
		Pounds				*Per cent*
1918 [2]	25 per cent ad valorem		$12,973	$3,243		25.00
1919	do		17,582	4,395		25.00
1920	do		45,693	11,423		25.00
1921	do [3]	(5)	[5] 28,984	[5] 7,345		25.34
1922 [4]	do [3]	(6)	[6] 17,530	[6] 4,608		26.29
1922 [7]	35 per cent ad valorem	2,105	4,163	1,457	$1.98	35.00
1923	do	18,920	21,510	7,529	1.14	35.00
1924 [8]	do	20,004	26,343	9,220	1.32	35.00

[1] Not recorded separately prior to July 1, 1918.
[2] From July 1 to Dec. 31, 1918, inclusive.
[3] Plus 7 cents a pound on those containing cotton having a staple of 1⅛ inches or more, under emergency tariff act of May 27, 1921.
[4] From Jan. 1 to Sept. 21, 1922, inclusive.
[5] Includes imports valued at $26,694 (quantity not stated), dutiable at 25 per cent ad valorem; 1,527 pounds, valued at $2,259, dutiable at 25 per cent ad valorem and 7 cents a pound, and imports, quantity not stated, valued at $31, imported from Philippine Islands duty free.
[6] Includes imports valued at $8,886 (quantity not stated), dutiable at 25 per cent ad valorem, and 3,233 pounds, valued at $8,644, dutiable at 25 per cent ad valorem and 7 cents a pound.
[7] From Sept. 22 to Dec. 31, inclusive.
[8] Preliminary figures.

Germany, France, and England are the main sources of imports.

COMPETITIVE CONDITIONS

In cords and tassels of the ordinary types, made of cotton yarns of coarse or medium counts, there is practically no competition from abroad. The small amount of imports includes articles made of fine yarns or metal tinsel threads, mainly of specialties in which labor constitutes a relatively large proportion of the total cost.

TARIFF HISTORY

Imports of cords were specially provided for in the cotton schedules of the acts of 1883, 1890, 1894, and 1897, the rates being 35 per cent ad valorem, 35 cents per pound (but not less than 40 per cent ad valorem), 45 per cent, and 45 per cent ad valorem, respectively. In the act of 1909 cords of cotton were not mentioned under the cotton schedule, but were classed with laces and embroideries under paragraph 349 of Schedule J, and made dutiable at 60 per cent ad valorem. Tassels, of cotton,[1] were mentioned for the first time in the act of 1913, paragraph 262, which provided for imports of cords, tassels, cords and tassels, of cotton or other vegetable fiber, at 25 per cent ad valorem. Paragraph 913 of the act of 1922 provides for imports of "cords, tassels, and cords and tassels; all the foregoing composed wholly or in chief value of cotton or of cotton and india rubber, and not specially provided for," at 35 per cent ad valorem. Imports of similar articles, made wholly or in chief value of other fibers, are provided for in other textile schedules of the act of 1922.

[1] Cords, cords and tassels, of wool, were included under the wool schedule in acts prior to that of 1913.

Court and Treasury Decisions

A cotton cord used in applique work, known as a coronation cord or braid, was held dutiable as cord and not as a manufacture of cotton. (G. A. 3736, T. D. 17750 of 1896.) Cords of cotton and india rubber, the rubber being the material of chief value, were held to be dutiable as cords of cotton or other vegetable fiber in part of india rubber under paragraph 263, and not as nonenumerated manufactures of which india rubber is a component material under paragraph 352. (G. A. 3019, T. D. 15995, of 1895, affirmed *Hague* v. *United States*, 73 Fed. 810 of 1896, affirmed without opinion, 89 Fed. 1017.)

Under the act of 1897 cotton coronation cord of the kind described in G. A. 3736, T. D. 17750, *supra*, was held to be dutiable as cord under paragraph 320 and not as braid under paragraph 339. (G. A. 4113, T. D. 19156 of 1898.)

In view of the former decisions, together with subsequent practice and legislation, it was assumed that Congress used the word "cord" in paragraph 349 with the same meaning as had been attached to it under previous acts, and so-called coronation cord was held dutiable under that provision. (*Ulmann* v. *United States*, 5 Ct. Cust. Appeals, 357 of 1914.)

A cord is a string or small rope composed of several strands twisted together. Cord which has not been twisted in any way was consequently held not to be dutiable under the provisions for cords as that term was used in paragraph 349, but to be dutiable as a manufacture of cotton. (*Ulmann* v. *United States*, 4 Ct. Cust. Appeals, 77 of 1913.)

Ornaments known variously to the trade as "drop ornaments," "trimmings," "tassels," "cords and tassels," and "silk tassels," composed chiefly of silk cords and threads but in part of other material, including "soutache" braid and wooden or pasteboard molds, and fashioned by knotting the cords into designs so elaborate that they lost their continuity and identity as cords, were held not to be dutiable under paragraph 316 of the act of 1913 as "cords," or as "cords and tassels." They were tassels, but there being no provision in paragraph 316 for "tassels" as such, they were held to be dutiable as ornaments or trimmings under paragraph 358 of that act. (*Willenborg* v. *United States*, 6 Ct. Cust. Appeals, 451 of 1915.)

V. SPINDLE BANDING

General Information

DESCRIPTION AND USES

Spindle banding may be a round cord, made by doubling and twisting strands of yarn or hard twisted roving, or it may be a narrow tape specially designed and woven for the use intended.

Spindle banding is used on spinning and twisting "mules," on ring spinning and twisting frames, and on spooling frames, for the purpose of transmitting power from the revolving drum or cylinder of the machine to the spindles, causing them to revolve. The drums or cylinders extend lengthwise of the machines and parallel with the spindle rails which contain the uniformly spaced spindle bases, and which, in turn, support the revolving spindles. While the "mule" may contain only one row of spindles, ring spinning and twisting frames and spooling frames are usually built symmetrically, with a row of spindles on each side and the drum or cylinder in the center of the frame, the axis of the drum or cylinder being a continuation of the driving shaft of the machine. The drum is usually a sheet metal cylinder, ranging from 7 to 8 inches in diameter and, in the case of cotton spinning frames, may revolve at speeds from 450 to 1,800 revolutions per minute, according to the ratio, in diameter, of the drum to the spindle "whorl," and the desired speed of the spindles, which in turn depends upon the nature of the product of the machine.

Each spindle is equipped with a "whorl" which, acting as a driven pulley, affords the driving contact with the spindle band. In order to attain the necessarily high spindle speed, the whorls are much smaller in diameter than the drum or cylinder, the diameter of the drum exceeding that of the spindle whorl by as much as five to nine times, so that the spinning spindles, on medium cotton yarns, sometimes attain speeds of over 9,000 revolutions per minute.

Up to a few years ago all spinning, twisting, and spooling spindles were equipped with whorls containing V-shaped grooves, adapted to the round type of spindle banding; for this reason, by far the greater proportion of spindles are still operated with round bands. In the use of the round band, each spinning or twisting spindle requires an individual band, which, extending around the horizontal driving drum and acting as a belt, makes a quarter turn upon reaching the whorl of the vertical spindle. Such round bands are made to length, one end having a doubled loop and the other terminating in the two separate strands forming the band. The band, in being "tied on," is threaded around the drum, and the ends gathered at the base of the spindle, each strand at the loose end being passed through the loop at the other end; a flat knot is used to tie the two strands together with the proper amount of tension in the band, the surplus stock of the ends being cut away. The band, now an endless belt, is then run

into the groove of the whorl of the spindle. The bands of spooling spindles using the round type of band are larger and longer than those on spinning spindles, each band being threaded in and "tied on" as above described, but making contact with two opposite spindles, one on each side of the frame. In this way, each band drives two spindles, except at the ends of the frames, where one band may be made to drive three spindles.

In the use of the round band, the tension is greatest when the band is first tied on. In operation it immediately begins to stretch and become slacker and slacker, finally breaking from wear and tear, generally at the knot. Where the band has not broken, it may eventually become so slack that the speed of the spindle is reduced through excessive slipping to such an extent that the yarn, lacking sufficient twist, becomes so bulky as to break down at the traveler, or so weak as to break at the rolls. In such cases the band must be cut off and replaced by a new one.

Because the speed of spindle must be constant and a uniform tension maintained in the driving band, practically all spinning, twisting, and spooling spindles of new machinery installed have been equipped with flanged and crown-faced whorls, driven with tape bands. Such frames are equipped with compensating idlers, one to each four spindles, around which the tape band makes contact and is guided for the proper routing.

In the tape band driving four spindles, the end of the band is led around the drum, around the whorls of the four spindles—two on each side of the frame—and around the compensating idler. The band is cut to the necessary length from the stock, the ends gathered under tension and lapped, and secured by stitching the lap through with a portable hand-stitching machine. In operation, the tape band thus acts as an endless belt under constant tension, maintaining the maximum spindle speed, and enabling the machine to deliver a product practically uniform in twist and strength. For this purpose the tape-band drive is superior to the round band.

In the various types of machines used for spinning, twisting, and spooling, great variations in the types and qualities of products call for corresponding variations in the sizes and types of spindles, which in turn, require suitable types of banding. For this reason, tape banding may vary greatly in width (from $\frac{3}{8}$ inch to 2 inches) as well as in texture.

In a frame using the round-band type of drive, the tape band can not be substituted for it without a complete change of spindle whorls and without the addition of compensating idlers and other necessary equipment. The cost of this remodeling is not justifiable under most conditions.

THE DOMESTIC INDUSTRY

History.—Textile spinning requires spindle banding, and the development of spindle banding has progressed with the demand for it. Round spindle banding, being the simplest and most easily made, was naturally first adopted, and the whorls of spindles adapted to it. Although the greater number of spindles in use are adapted to and require the round band, yet by far the greater number of new frames now being installed contain spindles adapted to the tape drive, which, introduced within the past few years, has proved the more satisfactory and economical.

Geographical distribution.—Common round spindle banding is generally produced in the plants where used. Most of that in the tape form is purchased from manufacturers who specialize in the various types called for by the trade; the greater portion is produced in the New England and Middle Atlantic States. Some large spinning plants using the tape-band drive are equipped with one or more specially designed narrow-ware looms for weaving their banding as required, and do not purchase any.

Organization and equipment.—In making spindle banding of the round type from yarn or roving, the only equipment required is a banding machine, which may be of the simple type, tended by an operative, or it may be one of the more modern automatic type. Tape spindle banding is woven on narrow-ware looms, machinery being also required for the preparation of the warp and filling yarns, generally purchased by manufacturers of the banding.

Methods of production and materials used.—The great bulk of ordinary round spindle banding is consumed by cotton spinning mills. At first, such banding was made of cotton yarns, but the perfection of the automatic banding machine has led to the general use of specially hard-twisted cotton roving, really the most satisfactory material.

In making the round band on the simple banding machine, the required number of ends of hard-twisted roving or yarn are gathered from a creel of bobbins into a strand, which is pulled through a guide by hand and looped to the projecting hook of one of a pair of mutually geared, horizontally revolving spindles. It is then drawn along the length of the frame toward the other end of the machine and around a horizontally sliding, counter-weighted hook, and back again toward the head of the machine, where it is looped to the projecting hook of the other horizontally revolving spindle and cut loose from the stock. The belt is then shifted from the idler pulley of the machine, and the horizontal spindles, actuated by the mated gearings, are caused to revolve rapidly in the same direction, thus putting the primary twist into the two strands. When, through the contraction caused by the twist, the sliding hook reaches a predetermined point, the belt is shifted to another fast pulley which, by means of a clutch, causes the two mated spindles to revolve as a unit but in the opposite direction, the final twist combining the two original strands into one. When the sliding hook, through the extra contraction, has reached a certain point, the machine knocks off. The band, which is then completed and of a uniform length, is detached from the sliding hook, and the two strands at the other end are cut loose from the hooks of the revolving spindles. This cycle of operations is repeated for the production of each band, the machine calling for the constant attention and manipulation of an operator. With the automatic banding machine, practically the same operations are performed in detail, but the necessary attachments enable the machine to act continuously and automatically repeating the cycles over and over after having been equipped with the necessary stock and properly started. Most cotton-spinning plants using round bands are now equipped with the automatic banding machine.

Very long life is not expected of the ordinary round band. Its durability depends upon various factors, such as the size and twist of the yarn or roving from which it is made, the quality and staple of the cotton entering into it, the tension under which the band is tied

on, the diameter of the spindle whorl, the size and speed of the spindle and the load. Atmospheric conditions within the spinning room also affect the life of the band. Bands made of roving do not last as long as those made of yarn, but they are preferred on account of the stretch before breaking, in the case of the roving band, being considerably less; as a consequence, in a spinning room where roving bands are used, better yarn will be produced. Practical experience has shown that one modern automatic banding machine will furnish sufficient roving bands for an equipment of 40,000 to 50,000 cotton-spinning spindles, producing medium or print-cloth yarns under ordinary conditions.

The average cotton spinning mill using round bands generally produces them within its own plant; some small spinning plants, however, may purchase round bands from other mills. Where several small mills in the same locality are under one management, it is customary for all the bands required to be made at one of the plants.

Some large spinning plants equipped with the tape band drive also weave their own tape banding, using their own yarns for the purpose; to that end they are equipped with one or more narrow-ware looms specially designed for the purpose. But the mills using woven-tape banding generally purchase it through supply houses or directly from the manufacturers.

Another type of round-spindle banding, used largely in worsted spinning, is made of two strands of yarn, twisted and doubled and counter twisted, but with a doubling of the ends of the strands back into the stock, the bands being completed at a uniform length and with each end terminating in a loop. A separate band is required for each spindle, and in banding the spindle the ends of the band are brought together and connected with a suitable coupling-wire link.

A round type of spindle banding, recently developed by a domestic manufacturer, consists of a braided cord, spotted in the process of braiding at certain points according to the length required. In applying this band, it is led around the drum and the spindle whorl, the ends brought together, and the strands of one end, passing through the loop at the other, are drawn up by tension until the spots coincide; the ends are then tied and the surplus stock cut away. A braided band of this type is said to run with less slip and stretch, but its cost is greater than that of the ordinary band, and it has not been introduced commercially.

Tape spindle banding is manufactured in various widths, from three-eighths inch to 2 inches, and the thickness, weight, and texture vary according to the use required. It is woven both single and ply, the single weave being generally of herringbone twill.

Round bands may be made of grey cotton yarn, but are now generally made of hard-twisted cotton roving. Tape banding is generally woven of grey cotton yarns.

Experiments have been made with bands of pure flax, treated to prevent stretch and shrinkage during use, but while these may show extra strength it is very doubtful if they would prove economical in actual use.

Production and consumption of spindle banding are not recorded.

EXPORTS

Statistics of exports are not available.

IMPORTS

Imports of spindle banding are not recorded separately. Table 18 shows combined figures for imports of wicking, spindle banding, and lining for bicycle tires, from August 28, 1889, to October 3, 1913, inclusive, together with total figures for imports of wicking and spindle banding, from October 4, 1913, to December, 31, 1924, inclusive. The annual average of the above totals is very small, and that of the spindle banding, alone, is less. Imports consist mostly of small lots of special round banding for use in English worsted-spinning machinery installed in some few domestic worsted spinning plants. Small lots of tape-woven banding are also imported for the same purpose. Imports are generally from England.

TABLE 18.—*Lamp, stove, and candle wicking, woven, braided, or twisted, and spindle banding, of cotton (or other vegetable fiber)*[1]*—Imports for consumption—Revenue, 1895–1924*

Year	Rate of duty	Quantity	Value	Duty collected	Unit value	Actual and computed ad valorem rate
Fiscal:		*Pounds*				*Per cent*
1895 [2]	45 per cent ad valorem		$8,459	$3,807		45.00

[1] Includes "lining for bicycle tires" in years under act of 1894.
[2] From Aug. 28, 1894, to June 30, 1895, inclusive. Imports not recorded prior to act of 1894.
[3] From July 1 to July 24, 1897, inclusive.
[4] From July 25, 1897, to June 30, 1898, inclusive.
[5] From July 1 to Oct. 3, 1913, inclusive.
[6] From Oct. 4, 1913, to June 30, 1914, inclusive.
[7] From July 1 to Dec. 31, 1918.
[8] Plus 7 cents a pound if containing cotton having a staple of 1⅛ inches or more, under emergency tariff act of May 27, 1921.
[9] From Jan. 1 to Sept. 21, 1922, inclusive.
[10] Includes 12,142 pounds, valued at $6,232, dutiable at 25 per cent ad valorem and 5 pounds, valued at $2, dutiable at 25 per cent ad valorem and 7 cents a pound.
[11] 10,251 days, equivalent to 28.08 years.
[12] From Sept. 22, to Dec. 31, inclusive.
[13] Preliminary figures.

COMPETITIVE CONDITIONS

The ordinary round spindle banding used by domestic cotton mills can be made by them more cheaply than it can be purchased; further, banding of this type produced by domestic manufacturers for the trade has no competition from imports, owing to the comparatively low prices prevailing as the result of competition within the home market. This applies also to the special round banding with looped ends, except in a few instances where domestic worsted-spinning plants, equipped with English spinning machinery, arbitrarily insist on the use of the imported English banding, even at a greater landed price than that of the comparable domestic article. For the same reason small lots of tape-woven bands are occasionally imported.

Domestic bands are made of a better grade of cotton than that contained in the imported article.

TARIFF HISTORY

Spindle banding was not mentioned in the tariff acts prior to 1894. Imports of spindle banding, made of cotton or other vegetable fiber, were made dutiable at 45 per cent ad valorem in the act of 1894, paragraph 263; at 10 cents per pound and 15 per cent ad valorem in the acts of 1897, paragraph 320, and 1909, paragraph 330; and at 25 per cent ad valorem in the act of 1913, paragraph 262. Paragraph 913 of the act of 1922 provides for imports of "spindle banding, made of cotton or other vegetable fiber," with the compound duty of 10 cents per pound and 12½ per cent ad valorem.

FOREIGN PRODUCTION

Spindle banding is necessarily produced in connection with spinning in all countries where yarns are manufactured, but there are no statistics available as to foreign production. Spindle banding forms an unimportant item in the small-wares group. As stated, most mills produce their ordinary bands as needed and can purchase the necessary types of tape banding in the domestic market to advantage. Because of the nature of the article, the same conditions seem likely to hold good in each country where the spinning industry is carried on.

PRICE DATA

There are no published price quotations on spindle banding. Any price named will depend upon the price of cotton at a given time, the type of band, its construction, and the quantity under consideration. A large domestic manufacturer states that the price is regulated by the competition among domestic dealers and manufacturers and is on a basis that allows very little profit, this condition resulting in prices underselling landed imports.

A statement of this manufacturer, dated February 28, 1923, gives data, on the pound basis, as follows:

	Cents
Average selling price of tape and round band	65.8
Average cost of yarns	36.7
Average expenses	28.0
Average cost, including yarn	64.7
Average profit per pound	1.1

About the 1st of February, 1923, this manufacturer imported some round endless banding from England for a special customer, for use in English worsted-spinning machinery. The English price was 2s. 6d. (58.4 cents) per pound, which, including the duty, totaled 75.7 cents per pound, exclusive of freight and insurance. Some five-eighths-inch tape banding was also imported, which cost, retail price, in England, as a small special lot, 3s. 6d. per pound; this, together with the duty, amounted to $1.02 cents per pound, not including freight and insurance. This manufacturer maintains that domestic bands are underselling the English bands by from 30 to 40 per cent.

WAGE AND COST DATA

Spindle banding not being separately classified, no information is available as to domestic wages and costs, nor is information available as to foreign wages and costs. Labor cost is a small item in the case of round banding, while in the case of tape-woven banding the combined items of labor cost and overhead expense may amount to 40 per cent of the total cost.

COURT AND TREASURY DECISIONS

Cord, one-quarter of an inch in diameter, composed of numerous strands of cotton yarn, hard-twisted and doubled, and designed for use in textile machinery for transmitting power, was held to be dutiable under paragraph 263 as "cords" or "spindle banding" at 45 per cent ad valorem and not as an unenumerated manufacture of cotton at 35 per cent under paragraph 264. (G. A. 4070, T. D. 18873 of 1898.) Such cord was likewise classified under the act of 1897. (G. A. 6462, T. D. 27664 of 1906.)

The provision in paragraph 330 of the act of 1909 for "banding for machinery" was held to be more specific than the provision for tapes not specially provided for and the provisions for webbings. (Abstract 33196, *Nairn Linoleum Co.* v. *United States*, 3 Ct. Cust. Appeals, 394, of 1913; see G. A. 7492, T. D. 33731 of 1913.)

VI LAMP, STOVE, AND CANDLE WICKING

General Information

DESCRIPTION AND USES

Wicking used in the manufacture of candles, and wicks, used in lamps and stoves, are so familiar that any description of them in pamphlet of this kind appears unnecessary.

Candle wicking is usually produced by twisting, cabling, or braiding yarn or threads. The type is composed of a wire of fuse-metal alloy, [illegible] with cotton threads; the threads of yarn afford the [illegible] capillary expansion, and the fusible wire serves to hold the [illegible] at the top when burning, the wire melting at the end as [illegible] Wicks of this kind are used in candles for [illegible]

[illegible] wicking is generally a woven narrow fabric, and of a [illegible] or flat formation. It is generally woven flat, in the double [illegible] with a hollow warp. A loose picking warp [illegible] of maximum [illegible] producing a hemispherical flame. The [illegible] is made from threads of an inch in. Another [illegible] is called human's lamps and stoves. It is a [illegible] this kind is woven as [illegible] the middle of [illegible] the warp is the [illegible] with an [illegible] [illegible] [illegible]

Geographical distribution.—One standard textile directory shows the distribution of plants manufacturing wicking as follows: Six in Massachusetts; 3 in Connecticut; 2 each in Rhode Island, New York, Pennsylvania, and Kentucky; and 1 each in Alabama, Illinois, Indiana, Maryland, Ohio, Oklahoma, and Tennessee.

Organization and equipment.—No statistics are available as to the organization and equipment of plants engaged primarily in the manufacture of wicking. In large plants where general lines of small wares are produced, wickings are made on machines that can be switched on or off for other products. Looms and braiding machines used in the production of wickings are included with those grouped under the small wares heading.

Materials used.—Lamp and stove wickings are generally constructed of medium and coarse cotton yarns, usually of low-grade stock, although in braided wicks cotton rovings are used as a core. Cotton is practically the only fiber used, although it, or even all cotton, the wording of paragraph 913 of the act of 1922 includes wicking made of other vegetable fibers.

Methods of production.—There are three general types of wickings: braided wicking, flat-woven wicking, and tubular-woven wicking.

Braided wickings are generally not braided solid, but around an inner core, usually of soft cotton roving.

Flat-woven wickings are made on the ply-fabric principle with coarse ply warp yarns and finer ply filling yarns.

Tubular wickings are also ply-woven of coarse yarns, some of the two-ply warp, soft-twisted, and the three-ply filling.

Woven wickings are products of narrow-ware looms equipped for developing the various types. Twisted wickings are developed in machines designed for the purpose. In the production of wickings, dyed threads are sometimes introduced for advertising or trade-mark purposes and for the same reason some wicks may be constructed entirely of dyed yarns.

Designing, drafting, and yarn preparation: Descriptive details covering these stages of manufacturing are fully outlined elsewhere under the heading of small wares. The yarn generally used in wickings being rather coarse, of short staple, and of low-grade stock, is easily and economically produced in plants that do their own carding and spinning. In plants where no carding or spinning is carried on, yarns are purchased as required, generally in condition best suited for subsequent handling with a minimum of processes preparatory to braiding or weaving.

Finishing: Wickings after leaving the braiding machine or loom undergo practically no finishing process, being ready for shipment and packed for the trade. Cleaning and trimming are done in the yarn or in the raw stock.

Production and statistics of.—Statistics of small wares, all made wickings are not given separately from those of other small wares in the census reports.

IMPORTS

Imports are not separately [illegible] an indication of [illegible] the United States [illegible]

$32,000 in 1923, and $38,000 in 1924. As shown in Table 5, the United States supplies about seven-eighths of the total Canadian imports in this line.

IMPORTS

Imports of lamp, stove, and candle wicking are not shown separately, but in combination with spindle banding, and lining for bicycle tires. (See Table 18, p. 49.)

Sources of imports are not shown in the statistics. Imports of wicking at the present time are negligible. A consumer of candle wicking who uses both the domestic and the imported article states that the landed price of the imported article is practically the same as the price of the comparable domestic article.

TARIFF HISTORY

Lamp, stove, and candle wicking was not mentioned in the acts of 1883 and 1890. The act of 1894, paragraph 263, provided for lamp or candle wicking at 45 per cent ad valorem; the act of 1897, paragraph 320, for lamp, stove, or candle wicking, at a compound duty of 10 cents per pound and 15 per cent ad valorem; the act of 1909, paragraph 330, for lamp, stove, or candle wicking, at a compound duty of 10 cents per pound and 15 per cent ad valorem; the act of 1913, paragraph 262, for lamp, stove, or candle wicking, at 25 per cent ad valorem. The present law, the act of 1922, paragraph 913, provides for imports of lamp, stove, or candle wicking, at a compound duty of 10 cents per pound and 12½ per cent ad valorem. In all the above acts, the provisions are for wicking made of cotton or other vegetable fiber.

COMPETITIVE CONDITIONS

A comparison of the import statistics shown in Table 18 with those of lamp wicks imported into Canada from the United States, as shown in Table 5, indicates that the value of Canadian imports of lamp wicks from the United States averages five times the combined values of the total imports into the United States of lamp, stove, and candle wicking and spindle banding. This, together with the fact that the greater portion of the Canadian imports are for the most part from the United States, would indicate that wicking is produced in the United States on a competitive basis with imports, especially in plants producing their own yarns.

Court and Treasury Decisions

Under the act of 1890 lamp wicking composed of four-ply soft cotton yarn having the general appearance of a braid or cord, but not commercially known as a braid or cord, was held to be dutiable as a manufacture of cotton, rather than as cotton cord. (G. A. 2536; T. D. 14853 of 1894.)

Merchandise claimed to be lamp wicking, shown as used in a kerosene lamp and as conducting kerosene to the flame after receiving it from another wick acting as a feeder, was held to be dutiable as lamp wicking and not as a manufacture of cotton. The board said, "This is the function of a lamp wick, and the fact that it is used in some particular kind of a lamp is, in our opinion, of no consequence." (Abstract 27624, T. D. 32161 of 1912.)

VII. BOOT, SHOE, AND CORSET LACINGS

General Information

DESCRIPTION AND USES

Boot, shoe, and corset lacings, made of cotton or other vegetable fiber, may be either round, flat, or tubular. The round may consist of strands of yarn or thread twisted or cabled together or of a solid, braided cord. The flat and the tubular may be either woven or braided. Some years ago a very wide woven silk lace was in demand for shoes, but at the present time (1924) practically all laces, round, flat, or tubular, are products of braiding machines. Lacings are made in different lengths, sizes, textures, and colors, and are finished with tips at the ends.

THE DOMESTIC INDUSTRY

History.—The development of the manufacture of lacings has kept pace with that of the articles calling for their use.

Geographical distribution.—Statistics are not available as to the manufacture of lacings as a separate industry. A standard textile directory lists plants engaged in the production of "laces, shoe and corset," as follows: Rhode Island, 37; Massachusetts, 25; Pennsylvania, 7; New Jersey, 6; New York, 5; Connecticut, Illinois, Ohio, 2 each; and Missouri, 1.

Organization and equipment.—No statistics are available as to the organization and equipment of plants engaged primarily in the manufacture of lacings. Although some large plants manufacture these as their chief products, many large plants turning out the general line of products of the small-wares trade make all types of lacings. The braiding machines and other equipment employed in the manufacture of lacings are not enumerated separately, but are included in the total equipment reported for the full line of cotton small wares. The equipment is mainly of domestic manufacture.

Materials used.—The chief materials used are cotton yarns, plain or mercerized. Some lacings, particularly for corsets, are made of silk and artificial silk, and some corset lacings also contain elastic rubber threads. One large manufacturer makes a line of corset lacings of elastic braid. Another, some years ago, made lacings from polished "iron yarn" imported from Germany. Lacings are made of bleached and dyed cotton yarns of all suitable colors. No flax is used in the domestic industry. Fine laces are made of staple cottons.

The tipping of the laces forms an important part of the manufacture. Tips stamped from metal are attached, rolled up and fastened by crimping or beading. Laces are also tipped with wires wrapped and twisted out to a point. Some laces of the finer types, bleached or colored, are tipped with strips of celluloid, colored to match, the celluloid being softened and cemented to the lace with an application of acetone. These are known as invisible tips.

Methods of production.—Boot, shoe, and corset lacings were in the main formerly produced as cords, by twisting, and were commonly

known as "strings." Some wide shoe laces are woven on narrow-ware looms, as are also certain types of corset lacings containing elastic threads. At the present time, however, boot, shoe, and corset lacings are produced almost entirely by braiding, and are made in flat, tubular, and cord types. In Section XI will be found a description of the braiding machine and an explanation of braiding operations applying also to the braiding of boot, shoe, and corset lacings. In the braiding of lacings, a machine or unit produces only one end or article. In a recent issue of a textile journal mention is made of a newly developed type of shoe-lace machine said to be capable of braiding as many as forty separate laces simultaeously, but the mechanical and technical details of the machine are not described.

Domestic production and consumption statistics of boot, shoe, and corset lacings are not recorded separately from those of other small wares.

EXPORTS

Exports of boot, shoe, and corset lacings are not recorded separately, but are known to exceed imports. Statements from the trade show exports to Canada, Brazil, Argentina, the Philippines, Cuba, and various other countries, including China. An indication of the extent of this trade is afforded by Canadian statistics, which show imports to Canada from the United States of "boot, shoe, shirt, and stay laces," valued at $18,376 in 1911, $18,232 in 1912, $42,788 in 1913, $35,959 in 1914, $49,910 in 1915, $141,467 in 1916, $271,886 in 1917, $145,721 in 1918, $227,005 in 1919, $247,833 in 1920, $188,246 in 1921, $84,704 in 1922, $110,527 in 1923, and $82,119 in 1924, all for fiscal years ended March 31. Of the total values of Canadian imports in this line the proportion from the United States amounted to 8 per cent in 1911, increased to 14 per cent in 1914, to 35 per cent in 1915, and to almost 95 per cent in 1917, decreasing later but amounting to 72 per cent in 1923, and to 58 per cent in 1924.

The above figures, together with other statistics, tend to show that domestic manufacturers are retaining a substantial portion of the export trade in lacings secured during the war.

IMPORTS

Imports for consumption, 1891–1924, of boot, shoe, and corset lacings are shown in Table 19. Quantities were expressed in pounds until 1914, in which year the gross (i. e., 12 dozen) was adopted as the unit of measure, but the pound is again used under the act of 1922. The origin of imports is not shown in the statistics, but Germany is normally the main source, with smaller amounts from England, France, and Belgium.

A comparison of imports for consumption of boot, shoe, and corset lacings with Canadian imports from the United States of boot, shoe, shirt, and stay lacings, from October 4, 1913, to September 21, 1922, inclusive, shows that in total annual values the former averaged about $13,000 while the latter averaged about $158,000. During the period of the act of 1913, therefore, American exports to Canada alone averaged annually about twelve times the total imports to the United States of boot, shoe, and corset lacings. In 1923 and 1924, this ratio has more than doubled.

TABLE 19.—*Boot, shoe, and corset lacings of cotton (or other vegetable fiber)*[1]—*Imports for consumption—Revenue, 1891–1924*

Year	Rate of duty	Quantity	Value	Duty collected	Unit value	Actual and computed ad valorem rate
Fiscal:		*Pounds*			*Per pound*	*Per cent*
1891[2]	35 cents per pound, with minimum ad valorem of 40 per cent.	278,413	$188,193	$102,770	$0.6760	52.61

[1] Includes cords and braids under acts of 1890 and 1894.
[2] From Oct. 6, 1890, to June 30, 1891, inclusive.
[3] Not recorded.
[4] From July 1 to Dec. 31, 1918, inclusive.
[5] Plus 7 cents a pound on those containing cotton having a staple of 1⅜ inches or more, under emergency tariff act of May 27, 1921.
[6] Included 2,107 gross (weight not stated) dutiable at 25 per cent ad valorem, and 1,425 gross (weighing 2,256 pounds) dutiable at 25 per cent ad valorem and 7 cents a pound.
[7] From Jan. 1 to Sept. 21, 1922, inclusive.
[8] Includes 2,706 gross (weight not stated) dutiable at 25 per cent ad valorem, and 192 gross (weighing 53 pounds) dutiable at 25 per cent ad valorem and 7 cents a pound.
[9] Annual average per year of 365 days, for the period covering five tariff acts from Oct. 6, 1890, to Sept. 21, 1922, inclusive. As this period included 11,673 days, almost exactly 32 years, the annual average was obtained by dividing the total imports during this period by 32.
[10] Sept. 22 to Dec. 31, inclusive.
[11] Preliminary figures.

COMPETITIVE CONDITIONS

It will be seen from the above that the domestic industry is well established, this being especially the case in lacings made of cotton yarns of coarse and medium numbers. Some lacings, however, are made from fine yarns of combed Sea Island cotton, but so long as these yarns are within the domestic spinning range, competition from imports is not great. One large domestic manufacturer, who spins and spins his own cotton yarns, states that his company exports to foreign countries, and that while there has hitherto been no competition from Europe, the competition among domestic manufacturers is so intense that manufacturing is profitable only on a [illegible] basis. He mentions the case of a special lace sold by his [illegible] at an actual loss of 10 per cent simply to retain orders against [illegible] competition. Several large firms, jobbing and importing [illegible], say that they are unable to import lacings to advantage at present prices and duties. Some jobbers of domestic and [illegible] import laces from England for customers who prefer the imported article to the domestic article of equal quality and [illegible] selling price.

TARIFF HISTORY

[illegible] and corset lacings of cotton were provided for in the act of [illegible], paragraph 334, at a specific duty of 35 cents per [illegible] and corset lacings made of cotton or [illegible] were dutiable at 45 per cent ad valorem in the act of [illegible], at 25 cents per pound and 15 per cent ad valorem in the act of 1909, paragraph 321, and in the act of 1913, paragraph 319, at 25 cents per pound and 15 per cent ad valorem. Boot, shoe, and corset lacings made of cotton or other [illegible] were dutiable in the act of 1922, paragraph 913, at [illegible] cents per pound and 20 per cent ad valorem.

[illegible] and Trade Conditions

[illegible] imports in lengths of from [illegible] laces by being [illegible] were held to be [illegible] the act of [illegible]

VIII. LOOM HARNESS, HEALDS, AND COLLETS

General Information

DESCRIPTION AND USES

Loom harness, of twine, when ready for use, is made up of healds or heddles, spread and spaced on shafts, and suspended in the loom frame by means of strapping, cords, or collets, each such frame of healds being known as a "shade." The harness equipment of an ordinary fly-shuttle cam loom consists of at least two and possibly more shades. In ordering harness for such looms, the specifications would include: The number of sets of harness, the number of shades per set, the number of eyes per shade and their spread on the shafts in inches, the depth of the shade inside or between the shafts, the dimensions of the shafts, the number of screw-eyes and their spacing in the top and bottom shafts, and the type of twine to be used in the healds. While the above plan covers the harness used in the ordinary fly-shuttle cam loom for the weaving of sheetings, shirtings, drills, ducks and other standard fabrics, including the greater portion of the cotton goods weaving industry, yet special healds, equipped with special eyes, usually of metal, and known as "couplings" are used as individual units in Jacquard weaving.

The heald or heddle, sometimes called the "eye," is a unit of the harness and its duty is to sustain and control the position of one single end or thread of the warp in the loom. The harness in a loom consists of two or more shades, each shade made of the proper number of healds, grouped and spaced on the shafts of that shade.

Collets are cords used for sustaining and actuating the "mails" used on Jacquard looms, referred to later.

In fly-shuttle cam looms the harness frames are usually supported by leather strapping, each strap containing a hook at one end for connection with the screw eye in the harness shaft. Strapping also extends from the harness jacks of the bottom shafts to the harness treadles, the movement of the harness shades being positive, both up and down, and controlled by the treadles, which in turn are actuated by the cams, this being the arrangement adapted for cam looms. Where the design of the fabric to be woven calls for a number of harness shades exceeding the practical possibilities of the cam motion, dobby shedding motions are adopted which increase the harness capacity up to 32 shades or separate harness units. While these shades could all be of standard twine harness, made of cotton or other vegetable fiber, as provided for in paragraph 913, yet, in practice, the harness shades in dobby weaving are generally made up of wooden frames containing an upper and a lower metal shaft, on which are strung detachable metal heddles; the latter may be made of special steel wire, doubled and soldered, or twisted, or finished from special flat wire, each heddle containing an eye about the center of its length and equipped with a loop at each end for suspension on the metal shafts. Metal heddles vary in size, length, and details for different uses. In the harness described above they are not fastened together in any manner and, up to the full capacity of each shade, any number necessary can be assembled in a frame.

In the case of twine harness, the number of eyes on a shade, and their spacing, are fixed, thus limiting the number of ends per inch that can be woven in the warp, except where weaves with fewer ends per inch may be produced by skipping eyes, at a uniform rate, in the web drawing, leaving a number of vacant eyes in each shade. For this reason, many cam looms are also equipped with heddle frames and metal heddles, where constructions in the weave room are frequently changed and where elasticity in designs is required, and where otherwise a large stock of twine harness of various capacities would need to be kept in reserve. While metal heddles enter largely into harness for weaving, they are not embraced in the classifications under paragraph 913, which includes only loom harness, healds, and collets made wholly or in chief value of cotton or other vegetable fiber. Metal heddles used in the domestic weaving industry are mainly manufactured in domestic plants; some are imported under schedule 3, paragraph 316, of the act of 1922.

When the pattern or design of the proposed fabric calls for a shedding of the warp threads beyond the capacity of the dobby, recourse is had to the Jacquard shedding head. In the healds used in Jacquard weaving, eyes known as "mails" are provided and may be of bronze or glass.

In advance of hanging up an ordinary loom for the weaving of a fabric, the prepared warp, consisting of the total warp threads that are to go into the product, is "drawn-in," each unit end or thread of the warp being drawn through its appropriate harness-eye, or heddle, according to the draft plan, and each end being subsequently drawn through the proper dent of the reed. The warp, on its beam or beams, along with the harness and reed, is placed in the loom, the harness frames secured by the collets or strapping, and the reed properly fastened in the lay of the loom. In the subsequent weaving the proper shedding of the different portions of the warp for the inserting of each pick of filling is brought about by lifting and lowering the harness shades in a predetermined manner, the use of the harness thus being manifest.

Twine harness when spread on the shafts is frequently equipped for use in the automatic warp-drawing machine. In this case, the eyes or healds are individually separated and held in the proper position by means of special spiral springs, which can be brought down near the center of the healds, when the shades are placed in the machine along with the reed; upon adjustment, the machine can be started and a selecting needle will draw each warp thread separately through the proper dent in the reed, as well as the proper eye of the harness.

Many manufacturers of twine harness are equipped for turning out loom twine harness adapted for use in the automatic warp-drawing machine at a minimum cost, much less than would be the case at the loom drawing plant. Web drawing or the drawing of the warp threads through the harness eyes and reed dents, is a tedious process when done by hand, a process now done by an automatic machine [illegible] the work of tying the ends of a new warp to the running ends of the old, and pulling the new ends through the harness and reed.

A [illegible] a mechanism for the separation of two sets of threads, [illegible] and the other, the [illegible] angles to the warp. These

threads in the fabric interweave with each other, according to design. The original, primitive manner of accomplishing this was by the tedious process of threading the filling through the warp by means of a needle. The earliest harness of record consisted of a series of twine loops, each passing around one warp thread and all fastened to a rod, the number of loops to the rod and the number of rods with loops depending upon the plan and the compass of the weave. In weaving, the proper shed was developed by drawing the proper rod, or rods, in advance of the remaining ones, the rods being moved by hand. The next improvement was the linking of a similar series of loops with those previously described, passing each around a second rod, and fixing all loops in properly spaced positions, or spread, on the rods. The modern twine harness is constructed on this principle. It will be noted from the above that the demand for harness began with the inception of weaving.

THE DOMESTIC INDUSTRY

History.—The domestic manufacture of twine harness, on a commercial scale, began over three-quarters of a century ago, with the domestic weaving industry, and has kept pace with the development and improvement of the modern loom. Loom harness is produced in plants equipped with modern automatic machinery. Since many plants manufacturing loom harness also make loom reeds, both reeds and harness can usually be purchased from the same manufacturer.

Geographical distribution.—A leading textile directory lists loom harness manufacturing plants as follows: New Jersey, 13; Massachusetts, 4; New York, 4; Rhode Island, 4; Pennsylvania, 3; South Carolina, 2; Maine, 1; North Carolina, 1. Although a greater number of establishments are found in New Jersey than in any other State the capital invested is proportionately less than in some other States. For instance, the capital of one large plant in another State almost equals the combined capital of the New Jersey plants. But a large portion of the silk-weaving industry is located in New Jersey, and the majority of the loom harness manufacturers there produce a twine harness of a very fine quality for silk weaving and of a style different from that used in the weaving of ordinary cotton fabrics.

Organization and equipment statistics are not available.

Materials used and methods of production.—Loom harness, in the past, has been made of worsted, linen, silk, and cotton, but at present it is made chiefly of cotton. While it is estimated that fully two-thirds of the domestic looms are equipped with twine harness of cotton, the harness in use is generally of two types. The greater portion used is for the weaving of cotton fabrics, and is made from twines cabled or twisted from cotton yarns ranging from 20s to 78s. One large manufacturer estimates that from 300,000 to 400,000 pounds of domestic twine are consumed annually. In the weaving of silk, a twine harness of great fineness and strength is required, and while a considerable portion of this fine harness is imported, a satisfactory type is produced in the domestic industry from 70s to 100s twelve-ply cotton yarns. The combed Egyptian cotton yarns and the finest cabled cotton twines for the manufacture of such fine harness are generally imported, ranging from 98s twelve-ply to 150s nine-ply; for some purposes twines as high as 200s nine-ply have been imported. Imports of these fine harness twines have ranged

from 25,000 to 60,000 pounds annually. A small proportion of the finest imported is polished, it being held that the polishing of the twine adds to the life of the harness. In the manufacture of the finer harness cotton twine, England practically has a monopoly, as in the case of the finest yarns for labels and other fine weaves.

In the common domestic twine harness for use in fly shuttle looms, the heald consists of a strand of twine dropping down the required distance from the upper shaft, doubling back and looped to form the "eye" or opening of the required size, then returning to the top shaft, and there being knitted to the previous strand and looping over the shaft, again dropping to the center of the shade, again forming an "eye," the cycle being repeated for the forming of each "eye." From the bottom shaft an end of twine arises, going through the bottom of the "eye," and drops again to the bottom shaft, looping around it, and again rising to engage the next "eye," the operation being repeated for each "eye" as made. The twine healds, being strung and spaced on the shafts, are stretched tight and varnished at and near the eyes and for a distance each way with successive coats of a special varnish, each coat being allowed to dry thoroughly before the application of the next. After each coat, the healds are brushed and whipped to prevent any from adhering together. The varnishing of the twine is for the purpose of producing a protective wearing surface, prolonging the life of the harness in use, and preventing the chafing of the warp yarn in weaving. Harness of this type goes to the consumer already spaced on the shafts, which may vary from 12 to 14 inches apart, the shafts containing also the necessary screw-eyes properly attached, the harness being complete and ready for the web-drawing process. When harness is to be adapted for use in the automatic web-drawing machine, the necessary separating springs and rods are generally supplied and attached by the manufacturer, who is equipped for doing this at a minimum cost.

In Jacquard weaving, the "eyes" in the cords are made of brass, bronze, or glass and, as already noted, are called "mails."

In the domestic manufacture of fine twine harness for the ribbon and silk weaving trade, a type of construction is employed in which four strands of twine are required to accommodate each end of the warp. Although containing double the number of strands of twine in the imported article, it is manufactured comparatively cheaply, because the method is simply one of looping, without any braiding or knitting.

Collets may be made by braiding or twisting fine cabled cotton yarns.

Production and consumption figures are not tabulated in the statistics for loom harness, healds, and collets. As the annual imports for consumption have averaged a little over $9,000, and consist mainly of the finest types of healds for ribbon and certain types of silk weaving, it is evident that the domestic industry practically supplies the domestic demand for loom harness of the standard type used in weaving on fly-shuttle looms. The domestic product is practically consumed in this country.

EXPORTS

Exports of loom harness, healds, and collets are not separately recorded.

IMPORTS

Table 20, covering the period from July 25, 1897, to December 31, 1924, shows the imports for consumption of loom harness or healds under the act of 1897, of loom harness, healds, or collets, under the acts of 1909 and 1913, and of loom harness, healds, and collets, under the act of 1922.

Imports consist largely of the finest healds for the ribbon and silk industry, and are generally from France, and at times from Switzerland.

[1] From July 25, 1897, to June 30, 1898, inclusive. Imports not recorded prior to act of 1897.
[2] From July 1 to Oct. 3, 1913, inclusive.
[3] From Oct. 4, 1913, to June 30, 1914, inclusive.
[4] July 1 to Dec. 31, 1918, inclusive.
[5] Includes 6,142 pounds, valued at $11,698, dutiable at 25 per cent ad valorem, and 569 pounds, valued at $2,114, dutiable at 25 per cent ad valorem and 7 cents a pound.
[6] Jan. 1 to Sept. 21, 1922, inclusive.
[7] Includes 3,305 pounds, valued at $3,859, dutiable at 25 per cent ad valorem, and 1,167 pounds, valued at $7,129, dutiable at 25 per cent ad valorem and 7 cents a pound.
[8] For 9,189 days, equivalent to 25.18 years.
[9] Sept. 22 to Dec. 31, inclusive.
[10] Preliminary figures.

COMPETITIVE CONDITIONS

The domestic manufacture of twine harness is confined largely to products of the standard type made of domestic twines of medium yarns and used in the general run of weaving in fly-shuttle looms. It is delivered to the consumer in condition for the process of web

drawing. The domestic demand for this type has hitherto been fully supplied by the domestic industry. Although there have been no competitive imports, it was reported that in 1923 a large manufacturer of cotton print-cloths imported 1,500 full sets of standard twine harness of this type from England, at a landed price, including duty, 30 per cent below the selling price of the domestic article. Imported harness of this type would land in the form of bundles of twine healds, the healds being knitted together at the end in the process of manufacture, and the additional expense of the necessary shafts, of stringing and spacing the healds thereon, and of the screw-eyes would fall upon the importing consumer, tending to offset to some extent the alleged difference in price. With this reported exception, imports of twine harness have consisted almost wholly of fine cabled and braided twine healds, in bundles, mainly for use on silk ribbon looms and in the weaving of skein-dyed broad silks, and have been of French or Swiss origin.

The largest imports of healds of this type come from France in bundles of 50,000 each. They vary from 15 to 17 inches in length, and are made of two strands each, of fine twine braided or knitted to form the openings for the eyes and loops; some of the healds are supplied with two "eyes" or "mails" for double-deck weaving. Imported healds of this type compete in the domestic ribbon and broad-silk weaving trade with the fine domestic healds previously described; and although the domestic type, owing to its construction, requires about twice as much material per end of warp as that used in the fine imported healds, the price of the domestic article is still on a competitive basis with that of the imported type, this being due to the smaller amount of labor and time required in its production. The domestic manufacturer has a further advantage when prompt deliveries of fine healds are demanded. He is, however, at a disadvantage in the matter of raw materials, as he is obliged to import his finest twines from England at landed prices that necessarily include the duties provided for fine yarns. There is no fine domestic harness in which the healds are formed in the same manner as in the competing imports.

Various types of Jacquard healds are also imported; these are equipped with brass, bronze, or glass "mails." They are generally imported in two sizes, 7 and 7 inches, or 7 and 9 inches, as to top and bottom spacings. The Jacquard healds are of a very fine cotton or linen yarn, plied but not cabled, and glazed. Healds for Jacquard weaving are imported from France.

There are no imports of fine harness from England. Some fine healds come from Switzerland, but a large domestic dealer asserts that their price is likely to be higher than that of the French makes, on account of differences in labor costs.

Imported Jacquard healds are generally from Lyons, and fine healds from St. Etienne, France. It is held in the trade that collets can not at present be imported at a profit.

Metal heddles are not included in paragraph 913 of the tariff act of 1922, being provided for in paragraph 316; yet, owing to the fact that at times such heddles supplant loom harness and healds of twine, it is of significance that such metal heddles are imported in competition with heddles of domestic manufacture.

TARIFF HISTORY

Imports of loom harness or healds, made of cotton or other vegetable fiber, or of which cotton or other vegetable fiber is the component material of chief value, were provided for in paragraph 320 of the act of 1897, at a compound duty of 50 cents per pound and 25 per cent ad valorem, but collets were not specially mentioned. In paragraph 330 of the act of 1909, imports of loom harness, healds, or collets, made of cotton or other vegetable fiber, were provided for at a compound duty of 50 cents per pound and 25 per cent ad valorem; and in paragraph 262 of the act of 1913 at 25 per cent ad valorem. In paragraph 913 of the present law (act of 1922) imports of loom harness, healds, and collets, made wholly or in chief of cotton or other vegetable fiber, are made dutiable at 25 cents per pound and 25 per cent ad valorem.

FOREIGN PRODUCTION

No statistics are available for foreign production of loom harness, healds, and collets.

PRICE DATA

Standard cotton twine harness is generally purchased in the domestic market complete, ready for web-drawing and hanging-up in the loom. The price per set of such harness depends upon the material, size, and type of twine used, the number of eyes per shade and their spread, the depth of the shade, the number of shades per set, the size of the wooden shafts, and the number of screw-eyes. Such harness is also frequently adapted for use in automatic warp-drawing machines by the addition of heald-separating and spacing spiral springs and rods, this generally being done by the manufacturer, at a small advance in price, and much below the corresponding cost of the same work if done at the weaving mill. Harness, so completed, is shipped in crates to the consumer. In the domestic market, standard price lists adopted by the trade are available for harness of different types, and competitive net prices quoted by manufacturers are practically identical. The price per set of domestic standard harness is made up of the price of the shafts, the screw-eyes in the shafts, and the total healds or harness eyes in the set, the price of the harness eyes being affected to some extent by the number per inch, as well as by the size and type of twine used.

CONCLUSIONS

Owing to dissimilarity in the details and methods of construction of the domestic article and of the imported types, as outlined, comparative costs per pound would be of no value. Under present conditions the fine healds from France and Switzerland, previously described, are imported for use in certain branches of the weaving industry, in competition with domestic products adapted to the same purpose. The reported import in 1923 of 1,500 sets of standard twine harness for common cotton weaving may indicate the possibility of imports of this type competing with comparable domestic products.

COURT AND TREASURY DECISIONS

There are no decisions of importance on loom harness, healds, and collets, wholly or in chief value of cotton or other vegetable fiber.

IX. LABELS FOR GARMENTS OR OTHER ARTICLES

General Information

DESCRIPTION AND USES

Labels for garments or other articles, composed of cotton or other vegetable fiber, imports of which are provided for in paragraph 913 of the act of 1922, are assumed to be woven although not so specifically stated. The bulk of labels imported under this paragraph are woven on narrow-ware looms, and with fast edges.

Cotton woven labels are generally used on garments that are to be washed or laundered, manufacturers of such garments generally having their individual styles of labels, which serve as trade-marks for the identification and advertising of their products. In recent practice labels are also being attached to indentify cloths of established reputation from which some garments are made.

The lettering and figured designs in woven labels are produced in the process of weaving by the introduction of yarns of different colors, the ground weave being usually of bleached yarns.

THE DOMESTIC INDUSTRY

History.—The manufacture of woven labels for garments originated in England but imports now come largely from the Barmen district in Germany. The highly successful domestic weaving of labels is due to the perfection of the domestic ribbon loom with the Jacquard head, including all necessary modern equipment; also to the technical experience of the executives of the industry, many of whom learned its details in the Barmen district. The largest domestic plant was established in 1888 and incorporated in 1896. Labels were first specifically mentioned in the act of 1897.

Geographical distribution.—Statistics are not available as to the manufacturing of labels for garments as a separate or distinct industry. One of the leading textile directories lists label-weaving plants as follows: Nine in New Jersey, 4 in New York, and 1 each in California, Connecticut, and Pennsylvania; one of the domestic companies also controls a plant in Ontario.

Organization and equipment figures as to plants engaged primarily in the weaving of labels are not separately shown in the Census of Manufactures, but are included in the statistical data of the smallwares industry. Although the textile directory lists 16 plants, other large plants engaged in the manufacture of small wares are also equipped for the weaving of labels, especially those of medium weaves and grades, and the development of the industry has doubtless advanced greatly beyond the above figures. In the Senate Finance Committee hearings on the tariff bill, in 1922, it was stated that the total investment in the industry amounted to $8,000,000; that there were in operation between 1,200 and 1,500 looms; and that the annual pay roll totaled $1,500,000 for approximately 1,000 employees.

Materials used.—Cotton woven labels are made from cotton yarns, the ground of the labels being usually woven of bleached warp and filling. The ground weave is generally plain, the lettering and figures being developed in the process of weaving with the addi-

tion of fast-dyed yarns of different colors and shades. While labels of coarse and medium texture can be successfully woven from medium yarns, fine texture requires fine yarns, and labels of the finest texture and detailed designs call for finest yarns. In fine labels the warp yarns may range from 100s two-ply to 200s two-ply, mule spun, gassed, bleached, and prepared. In the selvages, warp yarns are at times used that average 80s two-ply. The filling yarn in the ground weave is generally 70s single. About 60 per cent of the labels contain red yarns, and these are generally of the Turkey-red dyed type, and about 60s two-ply. Approximately 20 per cent contain black yarns, Nos. 50s to 60s, and the remaining 20 per cent yarns of other colors. One of the largest manufacturers of fine labels imports his bleached fine yarns from England, and his fast-dyed yarns from Germany. The very fine yarns, mule spun, gassed, bleached, and prepared, are not made in the United States; and the fast-dyed yarns are imported on account of the demand for dyes that will withstand the abuse of the laundry, alkalis, and perspiration, and remain fast to light and not bleed in boiling. The filling yarns are generally regular ring-spun twist in the original.

It is stated in the trade that domestic 60s two-ply yarn can be mercerized and dyed by local job dyers, who will furnish a fast dye against bleaching and bleeding, but which will be uncertain against alkalis. It is now possible, however, to obtain domestic fast-black dyed cotton yarns in medium numbers that will meet all the requirements for a label. Of the labels used in shirts of a certain popular and standard brand, those containing fast-black yarns are of domestic manufacture and contain domestic yarns exclusively. For the very fine yarns domestic gassing and bleaching are said to be unsatisfactory; although coarse and medium domestic yarns can be had of satisfactory bleach and finish, yet in the very fine numbers, if the bleach is sufficient, the yarn is so tendered that it will not stand the subsequent scouring processes.

Mercerized cotton yarns are also used, in fact, yarns mercerized before dyeing, are sometimes the more economical. (See Section I, under the head, Bleaching, dyeing, and finishing.)

Methods of production.—The subjects of yarn preparation, the narrow fabric loom, bleaching, dyeing, and finishing have been treated in detail in Section I—Fabrics with fast edges not exceeding 12 inches in width and articles made therefrom.

Most label-weaving plants purchase all yarns ready bleached or dyed, and merely perform the necessary operations of winding, warping, quilling, and web-drawing, preparatory to hanging-up the looms. The labels are woven with fast edges on narrow-ware looms, provided with Jacquard heads, and with from four to six banks of shuttles for varying the filling in each weaving space; the shuttle of each bank contains a separate filling, the shuttle being changed, according to the weaving design, while the loom is in operation.

The entire lettering and figured designs are completed in each unit or label, each complete repeat constituting one label, the repeats continuing as the loom operates, and the narrow fabric as produced being wound up as a ribbon. The line of separation for the cutting apart of the labels is indicated in the process of weaving by the proper change of filling on predetermined picks. The completed fabric is shipped in rolls to the consumer.

Production and consumption.—The production of cotton woven labels is not shown separately in the census statistics. While imports are shown separately, there are no recorded exports, and accurate deductions as to production and consumption are not possible. The annual value of the total products of one of the largest domestic plants exceeds $1,000,000.

EXPORTS

As exports of labels are not recorded, and as Canadian statistics show no imports from the United States, it is possible that the total domestic production, as well as the imports for consumption, is consumed in this country.

IMPORTS

Table 21 shows imports of labels for garments or other articles, composed of cotton or other vegetable fibre, for the period from July 25, 1897, to December 31, 1924, inclusive.

TABLE 21.—*Labels for garments or other articles composed of cotton (or other vegetable fiber)*[1]*—Imports for consumption—Revenue, 1898–1924*

Year	Rate of duty	Quantity	Value	Duty collected	Unit value	Actual and computed ad valorem rate
Fiscal:		*Pounds*				*Per cent*
1898[2]	50 certs per pound and 30 per cent.	6,123	$21,463	$9,500	$3.50	44.26
1899	do	7,481	25,023	11,247	3.35	44.95
1900	do	11,375	36,239	16,559	3.19	45.69
1901	do	9,147	28,666	13,173	3.14	45.98
1902	do	9,520	33,142	14,702	3.48	44.42
1903	do	16,985	55,384	25,108	3.26	45.33
1904	do	12,934	41,306	18,859	3.19	45.65
1905	do	13,991	47,822	21,342	3.42	44.63
1906	do	18,233	52,835	24,967	2.90	47.25
1907	do	19,587	56,027	26,601	2.86	47.48
1908	do	16,646	42,863	21,182	2.57	49.42
1909	do	8,172	22,656	10,883	2.77	48.03
1910	do	12,619	33,886	16,475	2.69	48.62
1911	do	4,906	17,585	7,729	3.58	43.95
1912	do	8,407	13,980	5,897	4.10	42.18
1913	do	4,285	13,758	6,270	3.21	45.57
1914	do	944	2,853	1,328	3.02	46.55
1914	25 per cent		23,378	5,844		25.00

1918	do		8,278	2,069		25.00
alendar:						
1918[3]	do		5,477	1,369		25.00
1919	do		5,831	1,458		25.00
1920	do		35,466	8,866		25.00
1921	do.[4]	(5)	38,304	10,020		26.16
1922[6]	do.[4]	(7)	126,305	32,927		26.07
Annual average[8]			32,338	12,751		39.38
1922[9]	50 per cent	12,406	30,488	15,244	2.46	50.00
1923	do	64,104	218,295	109,148	3.40	50.00
1924[10]	do	42,810	139,970	69,985	3.27	50.00

[1] Imports were not recorded separately prior to act of 1897.
[2] From July 25, 1897, to June 30, 1898, inclusive.
[3] From July 1 to Dec. 31, 1918.
[4] Plus 7 cents a pound if containing cotton having staple of 1⅜ inches or more, under emergency tariff act of May 27, 1921.
[5] Includes imports (weight not stated) valued at $14,486, dutiable at 25 per cent ad valorem, and 6,339 pounds, valued at $23,818, dutiable at 25 per cent ad valorem and 7 cents a pound.
[6] From Jan. 1 to Sept. 21, 1922, inclusive.
[7] Includes imports (weight not stated) valued at $14,300 dutiable at 25 per cent ad valorem, and 19,291 pounds, valued at $112,005, dutiable at 25 per cent ad valorem and 7 cents a pound.
[8] Annual average per year of 365 days for period covering 3 tariff acts from July 25, 1897, to Sept. 21, 1922. As this period included 9,189 days equivalent to 25.18 years, the annual average was obtained by dividing total by 25.18.
[9] From Sept. 22 to Dec. 31, inclusive.
[10] Preliminary figures.

Throughout the period covered by the acts of 1897 and 1909, imports were greatest upon the basis of value in 1907, amounting to 19,587 pounds, valued at $56,027. Subsequent to the peak of 1907, however, the values of annual imports show a decrease, falling to $13,758 in 1913. The increase in 1914 may have been due partly to the reduction in duty under the act of 1913.

The great bulk of imports having been from Germany in the past, the effect of the war is readily seen in the statistics for the five years ending with 1919. During this period of the war the change brought about in the domestic demand, owing to the fact that so many people were in uniform, admitted of the domestic demand being supplied by the domestic industry, with the addition of small imports, some of which were from England. The years 1920 and 1921 show decided increases, imports amounting to $35,466 and $38,304 respectively.

The greatly increased imports from January 1 to September 21, 1922, inclusive, were not due to any great extent to the anticipation of the higher duties, since the imports for the remainder of the year under the act of 1922 were almost of a proportionate value, and the total imports for 1922 were greatly exceeded by those for 1923, amounting to $218,295. Preliminary figures for 1924 show a considerable decrease.

Labels for garments are consumed by the manufacturers of garments, who dictate their designs and specifications and place orders for their supplies on the basis of competitive bids submitted by both domestic manufacturers and importers. Labels are not stock articles of unrestricted trade, as the designs in many cases are copyrighted. For this reason importers and domestic producers can not accumulate products in anticipation of prospective demand.

Although the country of origin is not shown in the statistics of imports, it is known that imports of cotton woven labels for garments are largely from the Barmen and Crefeld districts of Germany. Smaller amounts are supplied by England.

The upward trend of the value of imports beginning with 1920 was due partly to relatively prosperous conditions in this country, but more largely to the competitive advantage which importers enjoyed by reason of the depreciated and declining German exchange and the consequent low importing values. The table of imports shows foreign values.

Imports of labels under paragraph 913 of the act of 1922 are in chief value of cotton, generally of a plain weave for the ground, and of bleached yarns; and the designs, letters, figures, etc., are woven in, of fast-dyed yarns of cotton, although some also contain dyed yarns of artificial silk.

COMPETITIVE CONDITIONS

The manufacture of cotton woven labels, begun first in England, has developed to a well-established industry in Germany, where the art of weaving on narrow-ware looms with all modern attachments and equipment has been brought to a state of efficiency and perfection that may hardly be surpassed by the domestic industry. The lower wage scale in Germany is a competitive factor. Although orders on a quantity basis are greatly preferred, the ability and willingness of the German manufacturer to accept orders for small

lots is another factor in his favor. Germany also enjoys the competitive advantage of cheaper fast dyes of the types demanded in labels.

While some labels of medium texture may be produced satisfactorily from medium-fine domestic yarns, the bulk of the fine types calls for fine mule-spun yarns, 100s to 200s, two-ply, gassed bleached, and prepared; these are not produced by domestic manufacturers, but are imported from England. The rate of duty on imports of such yarns above 80s amounts to 30 per cent ad valorem, or 34 per cent ad valorem if vat-dyed, and the domestic label manufacturer who is compelled to import such fine yarns as his raw material necessarily pays the duty on them. As previously stated, the German manufacturer does not spin such fine yarns, and therefore also has to import them from England; but in weaving them into labels, and subsequently exporting his product to the United States, he enjoys the competitive advantage of immunity from duty on his yarns inasmuch as the German duty on imported yarns, which is lower than the American, is remitted when the labels are exported. It may be noted that, while under the present law imports of labels are dutiable at 50 per cent ad valorem, the comparable domestic product, made from the fine imported yarns, is not protected to that extent in competition with imports.

Prior to the stabilization of the mark on a gold basis in the fall of 1923, the German manufacturer also had the competitive advantage of his deflated currency in international trade.

The matter of freight hardly enters the question of competitive conditions, since the weight of 1,000 labels of average width and texture amounts to less than one pound.

Owing to unsettled conditions in the Ruhr Valley and adjacent territory in Germany, and the resulting delays in transportation, the domestic manufacturer has enjoyed an advantage in competing for orders wherein prompt and complete deliveries are demanded, domestic consumers at times cancelling their orders placed with importers, and at other times refusing to give repeat orders. But in large periodic or renewal orders, calling for uniform deliveries of an article constantly required by a large domestic garment manufacturer, maintaining a constant supply on hand, the German manufacturer has had all the advantages of lower wages and cheaper materials.

It is stated by a large consumer that the particular label which he uses, a standard make, woven with four colors, of a fine texture, is made abroad, and that on account of the four colors the imported article is more satisfactory; furthermore, that the landed price is 8¼ per cent below the price of the domestic competitive article. This label is purchased in large lots and for continuous consumption, and temporary delays in deliveries are not of serious consequence.

TARIFF HISTORY

Labels for garments were first specially mentioned in the act of 1897. Imports of labels for garments or other articles, composed of cotton or other vegetable fiber, were specially provided for at a compound duty of 50 cents per pound and 30 per cent ad valorem in the acts of 1897 and 1909, and at the rate of 25 per cent ad valorem

in the act of 1913. In the present law, act of 1922, the rate is 50 per cent ad valorem.

FOREIGN PRODUCTION

No recorded statistics are available as to the foreign production of labels for garments. Imports come from Germany, where, in the Barmen district, the weaving of labels has become a well established branch of the narrow-wares industry. Labels are also produced in England.

PRICE DATA

Sales of labels are generally made from samples, it being practically impossible to describe such goods by constructive specifications. For this reason there are no standard classifications upon which periodic quotations could be based. As previously stated, the item of freight, either on imports or on the domestic articles, is not an appreciable factor in the matter of competitive prices. For instance, one large domestic manufacturer ships a large proportion of his products by parcel post. In competing for orders, the quantity, deliveries, the number of different colored fast-dyed yarns, and the relative proportions in the sample label all enter the problem of price and margin of both the importer and the domestic manufacturer. Woven labels are the products of the narrow-ware or ribbon loom, each label constituting a complete design repeated over and over in the process of weaving, the fabric being woven into rolls, and sales of imports being generally reckoned on the price per 100 meters of the completed fabric. The length of one complete repeat for a particular label being known, the number of labels per 100 meters is readily ascertained; that being so, the price for competitive foreign and domestic bids can be based upon the label, using any arbitrary number, say 1,000, as a unit.

One firm of brokers reports its imports as averaging 36,000 meters per month, with prices ranging from $2.07 to $6.07 per hundred meters, based upon representative samples. These imports are for New York jobbers and come from Barmen.

One leading domestic consumer uses annually about 5,000,000 labels of a standard and well-established brand representing a very valuable trade-mark, woven with four fast colors and of very fine texture. He stated, in the spring of 1923:

> These labels made abroad cost us $4.80 per thousand as compared with the domestic quotation of $5.25. The reason why these labels of this character can not be made as well in this country as abroad is due to the fact that they are woven in four colors and as far as we know there are no four-color looms in this country that turn out as good labels as those made in foreign countries. Furthermore, the colors of the foreign make are far superior for reproducing our labels than domestic colors.

There is, however, no doubt that labels equally as good as any imported can be manufactured in this country from imported bleached and dyed yarns; but the higher cost of such yarns, landed duty paid, increases the difficulty of the domestic manufacturer in meeting the competition of imported labels.

Selling methods and margins also depend upon the conditions of the trade at any given time, whether it be a buyer's or a seller's market. Detailed information as to comparative prices of several

types of labels, imported from England and Germany and the domestic article, was given by a representative of the woven label manufacturers of the United States in a brief presented in the Finance Committee hearings on the tariff bill in 1922.

COST DATA

While many manufacturers purchase all yarns bleached or dyed, as the case may be, and simply prepare them for the loom, the manufacturing of labels in such cases being largely a matter of Jacquard designing, card cutting, yarn preparation, and weaving, yet other plants may be more fully developed with complete equipment for the bleaching, dyeing, and other manipulation of the yarns through all necessary processes. But plants are not standardized as to equipment and processes. Although one large plant may be fully equipped, owning its village, water power, steam, and electric plant, other label-weaving plants may consist simply of a few looms with the necessary yarn preparation equipment, and may be installed in rented buildings with leased power. For these reasons no comparisons as to first costs of mill and equipment in this country and abroad are feasible.

The materials used in the weaving of cotton labels consist mainly of cotton yarns, the finest types of yarns used being imported from England. Their comparative costs have been previously discussed under the head of materials, the effect of the duties on imported yarns being taken into account.

It is stated in the trade that in the manufacture of labels the item of labor usually constitutes over 40 per cent of the total cost of the product. No information is available as to overhead costs, which would vary with the organization, equipment, and size of the plant.

A very large and continuous consumer of a woven label containing fast black lettering of a simple design, for use in a high-class and popular shirt, purchases his labels from a domestic manufacturer who also controls a plant in England, but who at present supplies his customer from his domestic plant. On the other hand, a large constant consumer of a fine-texture label, woven with four fast colors, is able to secure his labels from Germany at a landed price 8½ per cent below the competing domestic article. These representative cases, in which the labels are bought and consumed in large amounts, and continuously, would appear to indicate to some extent the relative status of costs in Germany, England, and the United States.

COURT AND TREASURY DECISIONS

Under the act of 1890, cotton labels and shirt labels were held to be dutiable as manufactures of cotton and not as embroideries. (G. A. 2381, T. D. 14623 of 1893; G. A. 2530, T. D. 14847 of 1894.)

Labels, chief value of cotton, imported in strips, each strip containing several labels, were held dutiable under the provision for labels in paragraph 320, act of 1897. (G. A. 6271, T. D. 27053 of 1906, following T. D. 27009, 145 Fed. 622.)

Narrow woven strips of white cotton with single letters of the alphabet woven therein with colored threads at one-half inch intervals were likewise classified. (G. A. 4269, T. D. 20047 of 1898.)

Cotton strips about 2 inches wide, in which were woven, in silk, at intervals varying from 3 to 6 inches, the names of certain shoe companies, intended when cut to be attached to the tops of shoes, were held dutiable under the same provision. (*United States* v. *Herzog*, 145 Fed. 622, of 1905.)

Under the act of 1909 narrow strips of woven cotton fabric, black in color, about one-third of an inch in width, imported in running lengths and with cross-marks about 3 inches apart to indicate the points for cutting the strips into small pieces suitable for use as coat hangers, commercially fit for no other use, were held dutiable as manufactures of cotton at 45 per cent ad valorem under paragraph 332 of the act of 1909 rather than as cotton tapes at 60 per cent ad valorem under paragraph 349. (*United States* v. *Buss*, 5 Ct. Cust. Appls. 110 of 1914.)

Labels composed of cotton and silk, cotton component material of chief value, were held to be dutiable under the provision for "labels for garments or other articles" in paragraph 262 of the act of 1913 rather than as manufactures of cotton in paragraph 266. The Circuit Court of Appeals having decided that the provision of the tariff act of 1897 for "labels for garments or other articles, composed of cotton or other vegetable fiber" included labels composed of silk and cotton, cotton chief value (145 Fed. 622, *supra*), and the provision having been reenacted substantially in the act of 1909, and identically in the act of 1913, without substantial change of context, it must receive the same construction in the act of 1913, under the familiar rule that repeated enactments in identical terms of a tariff provision without substantial change of context, after the same has been judicially construed, will be accepted as legislative approval of the construction contained in that decision. (*United States* v. *Ascher*, 11 Ct. Cust. Appeals, 452 of 1923, followed in Abstract 45989 of 1923.)

X. BELTING FOR MACHINERY

Par. 913. * * * belting, for machinery, composed wholly or in chief value of cotton or other vegetable fiber, or cotton or other vegetable fiber and india rubber, 30 per centum ad valorem.

General Information

DESCRIPTION AND USES

Belting for machinery is a broad term, and the classification under the act of 1922, paragraph 913, includes belting composed wholly or in chief value of cotton or other vegetable fiber, and of cotton or other vegetable fiber and india rubber. Belting may be woven as simple or multiply fabric and of widths varying from the narrowest produced on narrow-ware looms to the widest and heaviest woven on fly-shuttle looms; it may consist of several plies of canvas or duck, folded and stitched and treated for use; it may be made of plies of heavy cotton fabric impregnated with rubber or balata gum, folded and stitched, and heavily calendered, and, in the case of rubber, subsequently vulcanized. These different types are all familiar to the trade and to the consumer.

Belting for machinery includes that used for the transmission of power as well as various types designed for conveying purposes. Imports of cotton transmission rope, for use in rope-drives, are also classed as belting for machinery, but comparable domestic products are classed as cotton rope. While a well designed and properly proportioned leather-belt drive will, under favorable conditions, generally prove the most efficient, especially when the belt is made endless, textile woven belts are coming more into favor. Where humid conditions are encountered, especially in the presence of steam vapors—conditions under which leather belts, even those constructed with water-proof cement, can not be used—textile belts impregnated with rubber are generally employed. For out-door drives, where belts are exposed to the weather, the rubber and balata are best suited. Balata belts are very satisfactory except under conditions of high temperature, as the gum begins to soften at about 120 degrees Fahrenheit. Both balata and rubber belts are efficient in pulley drives, owing to the high coefficient of friction. Special types of balata and rubber belts are manufactured for train-lighting purposes, the belts being installed under the coaches and driving the lighting dynamos from pulleys on the axles of the truck wheels. Special varieties of narrow-woven textile belting are treated and cut to lengths and sold as brake linings for automobiles.

A disadvantage of textile woven belts is the impossibility, for all practical purposes, of the consumer making them endless, it being necessary to employ belt fasteners of various types, or to resort to lacing. Both methods destroy the uniformity of the belt at the joint, and decrease its strength. A leather belt, on the other hand, can be taken up from time to time and made endless after each adjustment.

THE DOMESTIC INDUSTRY

History.—In 1891 the first products of the domestic rubber industry, in the line of hose, billiard cushions, and beltings, were placed on the market at Akron, Ohio, where manufacturing had been started on a small scale. Akron is now the rubber manufacturing center of the world. The manufacture of mechanical rubber goods began with that of hose and belting. The manufacture of rubber belting has also depended upon the development of the necessary fabrics employed in its construction. The same is true of balata belting, which is of more recent origin.

One of the largest domestic plants for the production of well-known brands of stitched duck and canvas belting was established in 1880. Another, in which textile woven belts of all kinds are produced, was established in 1834.

Geographical distribution.—Complete data showing the geographical distribution of plants engaged primarily in the manufacture of any of the types of belting embraced in the classification of paragraph 913 of the act of 1922 are not available. The Census of Manufactures for 1921 reported 31 establishments engaged primarily in the manufacture of belting and hose, made chiefly of cotton, linen, or canvas, distributed as follows: Five in Pennsylvania, 4 each in Massachusetts and New Jersey, 3 each in Indiana, Maryland, and New York, and 1 each in Colorado, Connecticut, Illinois, Michigan, Missouri, New Hampshire, Ohio, Rhode Island, and Virginia. Pennsylvania, the leading State, reported 34.7 per cent of the total value of products for the year.

In the same year 17 establishments reporting the manufacture of rubber belting and hose were located as follows: Five in New Jersey, 3 each in California and Illinois, 2 in Ohio, and 1 each in Delaware, Massachusetts, Minnesota, and New York. New Jersey, the leading State, reported 49.7 per cent of the total value of products.

Rubber belting was also reported in 1921 by establishments making rubber tires, tubes, and other rubber goods, located as follows: Ninety-six in Ohio, 64 in New Jersey, 52 in Massachusetts, 43 in New York, 37 in Pennsylvania, 26 in Illinois, 18 in Connecticut, 17 in Indiana, 15 in California, 11 in Missouri, 9 in Michigan, 7 each in Iowa, Rhode Island, and Wisconsin, 6 in Oklahoma, 4 each in Georgia, Minnesota, and Texas, 3 each in Colorado, Maryland, Nebraska, and Washington, 2 each in Kansas, North Carolina, Oregon, Virginia, and West Virginia, and 1 each in Delaware, Kentucky, Louisiana, and Utah. Ohio, the leading State, reported 50.6 per cent of the total value of products. Figures for the rubber industry in 1921 show that the total product of rubber belting amounted in value to $13,068,798, of which Ohio produced $4,130,403; New Jersey, $4,117,307; Massachusetts, $1,587,044; New York, $1,177,378; California, $828,800; and all other States, $1,227,866.

Textile woven belting for machinery is also made in cotton manufacturing plants engaged in the production of other lines of textiles; one of the largest plants in New England, making other goods, produced large quantities of woven belting, both on narrow-ware looms and on wide fly-shuttle looms.

Organization and equipment statistics for domestic plants engaged primarily in the manufacture of textile woven belting, canvas stitched belting, rubber and balata belting, are not available.

Materials used.—While belting for machinery may be composed wholly or in chief value of cotton or other vegetable fiber, or of cotton or other vegetable fiber and india rubber, the bulk of textile woven belting, from both the narrow-ware and fly-shuttle looms, as well as the canvas, duck, and twill used in the manufacture of the several types of belting previously described, are made of cotton yarns of various numbers and plies. Woven belting sometimes contains camels' hair yarns, woven in with the cotton yarns. Some canvas belts are impregnated with paints of linseed oil and metallic oxides, and some conveying belts of special types are saturated with paraffine wax.

Methods of production.—Woven belts of the narrower widths are produced on narrow-ware looms, and in the wider widths are woven on fly-shuttle looms. They are made of plied and twisted yarns, varying in both number and ply according to the purpose for which used. While the fabric may in some cases consist of a plain weave, the belts are usually of multiply weaves with a binding warp, the object being to construct a closely woven fabric of sufficient cross-section to withstand the tensile strains to which the belt is subjected when in operation and to develop a firm surface for contact with the pulley. The cotton and filling yarns used are generally of coarse and medium numbers and are prepared for the loom in regular processes. The looms, both of the narrow-ware and fly-shuttle types, are necessarily heavy and strong to resist the stresses arising in weaving such fabrics. The weave in this type may be either twill or plain, one manufacturer using a twill weave in belts up to 8 inches in width and a plain weave in the wider widths. Some of these belts are of double texture, the weave on one side being of camels' hair and the reverse surface of cotton.

Woven cotton belts are in some cases run through hot solutions of asphalt, pine pitch, or other ingredients for the purpose of preserving the surface, increasing the coefficient of friction, and rendering the belts water-proof.

In the manufacture of rubber belting, the cotton duck is impregnated with india-rubber gum, cut into widths according to requirements, folded into different plies and run between rollers, and, after being formed, subjected to pressure and vulcanized. Rubber belting is thus made in various widths and plies according to specifications. Belts so finished generally show on the surface the texture of the fabric, but some are also stitched through with longitudinal rows of machine stitching, given additional coats of rubber, and vulcanized, the fabric being thus completely covered and concealed. Balata belts are made of twill fabrics as well as of duck.

Belts are also made of canvas or duck, cut to desired widths, folded into plies, and stitched lengthwise with machine stitching; they are then treated with linseed oil products and the surface painted with mineral-oxide paints. Some belts of this type are treated to resist acid fumes and steam. Others, when completed, are saturated with paraffine wax, these being intended for conveyor belts for postal packages and other indoor conveying purposes, where cleanliness and sanitary conditions are of prime importance.

Some small cotton belts, particularly adapted to cone drives, are manufactured in the endless form, and subsequently vulcanized. One process of making small fabric endless belts is as follows: A double-cloth tubular-woven fabric, of a width equal to the length of the

required belt, is woven in a fly-shuttle loom. Two pieces of sufficient and equal length are taken, the edges of each piece turned in and folded, one piece being then inserted within the other, and the two pieces fastened together throughout their length with rows of stitching, thus forming a completed, endless belt. In this special type of belt, the filling threads of the original fabric constitute the ends running lengthwise of the completed belt, and this is taken into consideration in designing the tubular fabric for the purpose.

While many manufacturers of rubber, balata, and duck or canvas belting purchase the fabrics used, other large plants manufacture all the fabrics required.

Although in import statistics cotton transmission rope is classed as belting for machinery, in the domestic industry it is classed as cotton rope. Such rope is made in domestic cordage plants.

Production and consumption.—The domestic production of textile belting is not shown separately in census statistics, but in combination with hose, whose basic material is chiefly cotton, occasionally linen. The value of the combined products of these two articles amounted to $4,440,775 in 1914, $19,176,277 in 1919, and $6,390,498 in 1921. The apparent decrease from 1919 to 1921 was partly due to several important establishments having changed the character of their operations in 1921, being assigned to other classifications, such as "rubber belting and hose," "cotton goods," etc. Establishments assigned to other industrial classifications reported production of belting and hose, other than leather and rubber, to the value of $1,289,000 in 1914 and $1,168,000 in 1919. Corresponding figures for 1921 are not available, as they were not separately reported by the plants.

The production of rubber belting in establishments engaged primarily in the manufacture of rubber belting and hose amounted in value to $8,985,511 in 1919, and to $3,872,904 in 1921; in plants engaged in the manufacture of "tires, tubes, and other rubber goods," amounted to $13,450,000 in 1919 and to $9,087,000 in 1921.

For the rubber industry as a whole, the value of rubber belting in 1921 was $13,068,798. Preliminary figures for 1923, show a production valued at $24,266,881.

Domestic cotton transmission rope is classed as cotton rope, although imports of cotton transmission rope are classed as belting for machinery. Since the value of rubber belting products alone amounted to over $13,000,000 in 1921, while exports amounted to nearly $1,500,000, and imports of all kinds to only $232,169—mostly textile woven and transmission rope—it is evident that the domestic industry supplies practically the total domestic demand for rubber belting. The same statement practically applies to the domestic demand for other types of woven belting, imports of woven belting consisting generally of two specially woven types.

EXPORTS

Export statistics of cotton woven belting for machinery are not available. Exports of rubber belting were not separately listed previously to 1920, being included with those of "india rubber, belting, hose, and packing." The exports of this group totaled in value $2,605,551 in 1913, $4,525,243 in 1918, and $6,100,460 in 1919.

Exports of rubber belting to 75 countries totaled in value $3,532,277 in 1920, distributed as follows: British South Africa, $477,016; Mexico, $465,700; Canada, $270,939; Japan, $242,596; Chile, $239,927; Argentina, $200,337; Australia, $191,712; Cuba, $129,899; England, $98,721; Germany, $7,003; and the remainder to 65 other countries.

In 1921, exports of rubber belting to 68 countries, amounted in value to $1,446,063, distributed as follows: Mexico, $254,872; British South Africa, $214,893; Peru, $103,049; Canada, $84,358; British India, $64,014; Argentina, $54,709; England, $40,020; Germany, $3,077. The remainder went to 60 other countries.

In 1922, rubber belting to the value of $1,269,999, was exported to 77 countries as follows: British South Africa, $261,708; Mexico, $178,622; Canada, $122,672; Brazil, $81,545; Chile $61,094; France, $49,212; Argentina, $45,154; Australia, $44,283; England, $32,989; and the remaining $392,720 to 68 other countries.

Exports of rubber belting in 1924 amounted $2,089,056. Detailed statistics are not yet available.

IMPORTS

Imports of belting for machinery made of cotton or other vegetable fiber and india rubber were first specially provided for in the act of 1909. Table 22 shows imports for consumption of belting for machinery of cotton or other vegetable fiber and india rubber, from August 6, 1909, to December 31, 1924, inclusive.

TABLE 22.—*Belting, for machinery, of cotton (or other vegetable fiber)—Imports for consumption—Revenue, 1910–1924*

Year	Rate of duty	Quantity	Value	Duty collected	Unit value	Actual and computed ad valorem rate
Fiscal:		*Yards*				*Per cent*
1910 [1]	30 per cent ad valorem		$506,217	$151,865		30.00
1911	do		475,724	142,717		30.00
1912	do		173,185	51,955		30.00
1913	do		224,821	67,446		30.00
1914 [2]	do		63,908	19,172		30.00
1914 [3]	15 per cent ad valorem		248,451	37,268		15.00
1915	do		206,868	31,030		15.00
1916	do		286,518	42,978		15.00
1917	do		365,838	54,876		15.00
Calendar:						
1918	do		578,920	86,838		15.00
1918 [4]	do	323,801	353,114	52,967	$1.09	15.00
1919	do	516,286	550,970	82,645	1.07	15.00
1920	do	789,833	804,353	120,653	1.02	15.00
1921	do.[5]	[6] 407,643	232,169	34,843	.57	15.01
1922 [7]	do.[5]	355,365	265,189	39,778	.75	15.00
Annual average [8]			406,200	77,417		19.06
		Pounds				
1922 [9]	30 per cent ad valorem	49,364	59,257	17,777	$1.20	30.00
1923	do	565,081	374,802	112,441	.66	30.00
1924 [10]	do	555,686	377,650	113,295	.68	30.00

[1] From Aug. 6, 1909 to June 30, 1910 inclusive. Imports not recorded separately prior to Act of 1909.
[2] From July 1, 1913, to Oct. 3, 1913, inclusive.
[3] From Oct. 4, 1913, to June 30, 1914, inclusive.
[4] From July 1, to Dec. 31, 1918, inclusive.
[5] Plus 7 cents a pound if containing cotton having staple of 1⅛ inches or more, under Emergency Tariff Act of May 27, 1921.
[6] Includes 406,129 yards (weight not stated), valued at $231,537, dutiable at 15 per cent ad valorem, and 246 pounds (1,514 yds.), valued at $632, dutiable at 15 per cent ad valorem and 7 cents a pound.
[7] From Jan. 1, to Sept. 21, 1922, inclusive.
[8] Period of 4,795 days (13,14 years) covered by acts of 1909 and 1913.
[9] From Sept. 22, to Dec. 31, inclusive.
[10] Preliminary figures.

It will be seen that imports decreased from 1910 to 1913, and, in spite of the lowered duty under the act of 1913, did not increase during the years 1914, 1915, and 1916. This was possibly due to the war, as imports increased immediately after its close, reaching the peak in 1920. They fell off greatly in 1921, owing to the general slump in business during the period of deflation, but have since increased and during the past three years have remained fairly steady.

Imports of belting are largely from England, and during the war were almost entirely from that source.

In addition to imports of textile woven belting for the transmission of power, and of cotton transmission rope, other classes of belting for machinery are reported. These include different types of conveyor belts, composed of fine multiply fabrics, manufactured endless, and used in textile printing machines for sustaining the "back greys" and the fabric to be printed. Some of these types are also waterproofed, for use in the printing of wall paper.

There are at present practically no imports of rubber or balata beltings.

COMPETITIVE CONDITIONS

Special types of carrier belts used in textile printing machines for supporting the fabric and the "back greys," including those that are waterproofed, are imported from England as belting for machinery; these do not compete with any domestic article, there being no comparable domestic products at the present time. Woven beltings for the transmission of power, some containing camels' hair, are imported from England, and compete with comparable domestic products. One English company, constantly shipping to its American representative, contemplates the establishment of a domestic plant; the domestic representative asserts that the company's imports can hardly compete successfully at present with similar domestic products, although, in the case of the type containing camels' hair, the domestic manufacturer purchases his camels' hair yarns from spinners who import their raw stock at landed prices which include the duty. Textile belting for machinery of various widths and textures is constantly imported, but domestic manufacturers who also card and spin their yarns are able to compete successfully, under present conditions, with similar imported products.

Cotton transmission rope of a special type, varying in size from three-eighths inch to 2 inches in diameter, is continuously imported by a large corporation engaged in the manufacture and sale of transmission equipment, the imports being classed as belting for machinery. This rope, of a patented construction, is made of three strands and without a core, and is said by its manufacturers to reduce internal friction to a minimum. It is sold direct to consumers, and the importers state that it does not compete with any domestic identical article. Highly satisfactory domestic cotton transmission rope of different sizes and numbers of strands, with and without cores, is, however, readily available in the domestic market.

The domestic manufacturer of rubber and balata belting is at present meeting with practically no competition from imports. This situation is probably due to the efficient organization of the domestic industry in all its branches, including its control of foreign sources

of supply of raw materials, the manufacture of the various textile fabrics used, and its highly developed sales organizations. The last-named factor embraces successful methods of securing both foreign and domestic trade, some of the large companies maintaining stocks and having representatives in many cities of the United States as well as in the larger foreign cities. Domestic rubber belting is exported to most foreign countries. The large domestic manufacturers of stitched canvas belting are able not only to meet competition from imports but to find foreign markets for their products. There are occasional imports of special belts ordered by domestic users of foreign-built machines. Except for a relatively small amount of imported camels' hair, used in a certain type of woven belt, all yarns, fabrics, and other materials are of domestic manufacture.

TARIFF HISTORY

Under the tariff acts of 1883, 1890, 1894, and 1897, cotton woven belting was not specifically mentioned, and imports were dutiable under the basket paragraphs of Schedule I at 35, 40, 35, and 45 per cent ad valorem respectively. The first specific mention of belting for machinery in the cotton schedule was in the act of 1909 (paragraph 330) which provided for imports of "belting for machinery made of cotton or other vegetable fiber and india rubber, or of which cotton or other vegetable fiber is the component material of chief value," at 30 per cent ad valorem. The same wording was used in the act of 1913 (paragraph 262) but the rate was reduced to 15 per cent ad valorem. The act of 1922 (paragraph 913) provides for imports of "belting, for machinery, composed wholly or in chief value of cotton or other vegetable fiber, or cotton or other vegetable fiber and india rubber" at 30 per cent ad valorem.

FOREIGN PRODUCTION

No statistics are available as to the production of belting for machinery in foreign countries.

PRICE DATA

The different types of beltings for machinery are priced by the linear foot, and the price varies with the ply, the width, the construction and the quality of the article. Price lists are prepared by the manufacturer for each type and for all widths made. These lists represent the base prices, and are quoted in naming the discounts for the net prices, which depend upon the quantity under consideration.

Comparative wholesale prices have been obtained for roll lots, f. o. b. in the domestic market, as of June 1, 1914, the peak price of 1919 or 1920, and a recent price as of June 1, 1923, for the following standard types of belting: Imported textile woven, domestic balata, domestic canvas-stitched, domestic textile, and domestic rubber, all 8 inches wide and of the capacity of a first quality pure oak-tanned double leather belt. These, together with the price of such leather belt, are shown on the following page.

Wholesale net prices per linear foot, f. o. b. New York City, of belting for machinery, 8 inches in width, equivalent in capacity to an 8-inch pure oak-tanned double leather belt of best quality

Type	June 1, 1914	Peak (1919–20)	June 1, 1923
Imported textile woven	$0.620	$1.728	$1.310
Domestic textile woven	.507	.812	.619
Domestic canvas stitched	.350	1.010	.580
Domestic balata	.756	1.200	1.080
Domestic rubber	.780	1.320	.930
Domestic leather	1.422	3.072	2.688

Some manufacturers of belting for machinery sell directly to consumers, while others sell only through jobbers or supply houses. In addition to the price discounts from the base list, trade discounts are also allowed for cash.

WAGE AND COST DATA

No statistics are available for wage or cost data in the manufacture of belting for machinery, at home or abroad, as no investigations have been made. In all types described, domestic manufacturers equipped for carding and spinning their yarns, who also weave their fabrics and are producing on a quantity basis, are able to manufacture with minimum costs of materials, labor, and overhead.

COURT AND TREASURY DECISIONS

Machinery belting composed of cotton and india rubber, india rubber chief value, classified at 35 per cent under paragraph 463 of the act of 1909 as manufactures of rubber not specially provided for, was held to be dutiable, as claimed, at 30 per cent under paragraph 330 as "belting for machinery made of cotton or other vegetable fiber and india rubber." The court held that there was no ambiguity in the statute, the merchandise in issue coming directly within the terms of paragraph 330. (*Nairn Linoleum Co.* v. *United States*, 4 Ct. Cust. Appeals, 394 of 1913.)

In the case of *United States* v. *Pitt* (3 Ct. Cust. Appeals, 91 of 1912) the Court of Customs Appeals held that there could be no distinction between power transmission belts which are woven flat and those which are twisted cords, and that both alike are entitled to classification as belting for machinery.

In a later case, decided under the act of 1913 (G. A. 8036, T. D. 37063 of 1917), the Board of General Appraisers held that merchandise consisting of endless pieces of cotton felt, used for making conveyor belts in paper-making machines, for carrying paper pulp over hot cylinders for the purpose of drying it, was properly dutiable as belting for machinery. Paragraph 262 was construed to include the following articles: Blankets for cotton-printing machinery (Abstract 37188 of 1915); cotton felt for making conveyor belts (G. A. 8036, T. D. 37063 of 1917) as belting for machinery.

XI. BRAIDS, OTHER THAN BARMEN LACE[1]

TARIFF ACT OF SEPTEMBER 21, 1922

Par. 1430. * * * braids, loom-woven and ornamented in the process of weaving, or made by hand, or on any braid machine, knitting machine, or lace machine; and all fabrics and articles composed in any part, however small, of any of the foregoing fabrics or articles; all the foregoing, finished or unfinished (except materials and articles provided for in paragraphs * * * 1404, 1406, and 1424 of this Act), by whatever name known, and to whatever use applied, and whether or not named, described, or provided for elsewhere in this act, when composed wholly or in chief value of yarns, threads, filaments, tinsel wire, lame, bullions, metal threads, beads, bugles, spangles, or products of cellulose provided for in paragraph 1213 of this act, 90 per centum ad valorem; * * *

SUMMARY

The art of braiding is probably older than that of weaving, and, like weaving, was first done by hand.

Braiding by hand has been carried on among most tribes and peoples. The distinctive difference between braiding and weaving is that, in braiding, the threads of one series are crossed lengthwise, passing alternately over and under each other, making a texture of warp threads only, while in weaving, two series of threads are used, of which, one, the filling, traverses the other, the warp, at right angles. While weaving is by far the more important, many narrow fabrics used for tying, or ornamentation, could not be woven, and for these, the process of braiding was invented.

Plaiting or braiding is practically the mechanical application of the principle followed by the dancers in the well-known Maypole dance, dating back to the middle ages.

While some articles (lacings and wickings, for instance) included in the small-wares paragraph may be braided, most cotton braids are covered by paragraph 1430 of the act of 1922, and consist of articles for trimming purposes. The most popular type, other than Barmen lace, in the domestic as well as in the imported lines is known as rick-rack, a pattern developed by braiding with varying thread tensions.

PRODUCTION

Domestic braids are generally produced in plants manufacturing other lines of small wares.

In 1919 the domestic production of cotton braids, embracing "flat braids, woven and knitted," "lace and braided lace," "round braids" (including shoe and corset laces), and "all other," amounted to 1,119,890,689 linear yards, totaling in value $19,317,624. Census figures for 1921 show a total production of cotton "braided products" amounting to 1,995,202,285 linear yards, weighing 10,112,922 pounds, with an aggregate value of $13,025,750. The 1923 production was valued at $14,659,205 (preliminary figures).

[1] The fancy lace-like braids commonly known as "Barmen lace" will be treated in a survey dealing with lace, net, etc. Ordinary braids, other than Barmen lace, are considered to be more in the nature of small wares and therefore more properly treated in connection with the data herein given for other small wares. It should be noted, however, that import and export statistics do not separate Barmen lace from other braids and that there will necessarily be some overlapping of the data on braids in the two surveys.

IMPORTS

Imports for consumption of cotton braids, loom-woven and ornamented in the process of weaving, or made by hand or on any braid, knitting, or lace machine, amounted in value to $168,194 in 1920; to $172,378 in 1921; and to $291,898 from January 1 to September 21, 1922, inclusive. The decided increase in this portion of 1922 was partly due to the anticipated higher rate of duty under the act of 1922. Imports for the remainder of 1922 amounted to $63,519, and for the year 1923 to $157,829. Of the total imports of braids of all kinds during the periods above mentioned, more than half, by value, was of artificial silk, cotton braids ranking second, and silk braids third. The total braids imported in 1923 amounted in value to $656,708, distributed as follows: Cotton, $157,829; flax, etc., $5,745; silk, $64,154; artificial silk, $409,114; and braids of metal threads or tinsel wire, $19,866. Preliminary figures for 1924 show braids to the value of $608,346, distributed as follows: Cotton, $115,142; flax, etc., $3,435; silk, $42,643; artificial silk and horse hair, $426,546; and metal thread or tinsel wire, $20,580.

COMPETITIVE CONDITIONS

While braids of many types are standard, staple articles, some are subject to the dictates of fashion, and the demand is at times uncertain. Under present conditions domestic manufacturers are able to compete with imports in certain lines, but can not generally export in competition with German manufacturers.

General Information

DESCRIPTION AND USES

Braids are well-known articles in the trade and are used extensively for binding, staying, trimming, and other purposes.

It was not until the middle of the eighteenth century that the braiding machine was patented, the first official mention of a machine for making braid being an English patent granted to Thomas Walford, in Manchester, in 1848; but at that date the braid industry was already firmly established in Barmen, Germany, which may be truly called the birthplace of the braid industry. Braids were manufactured there long before the introduction of steam power, and to this day Barmen has a firm hold on the industry, sending braids to all parts of the world.

The cotton small-wares classification includes many braided articles, such as cords, tubings, sleevings, lacings, etc., but cotton braids, both the imported and those produced in the domestic industry, are chiefly for decorative and trimming purposes, two principal types consisting of the well-known "rickrack" and "soutache" braids. The name soutache is of Hungarian origin, and such braids are the simplest made.

Rickrack is also largely used in needle craft and crocheting for making edgings, insertions, and fancy trimmings; in the production of lingerie, bureau, luncheon and porch sets, pillow covers, curtains, doilies, baby caps, aprons, and innumerable other articles wherein braids of various sizes and colors can be used to advantage. Sou-

tache braids are finding new and extended uses in the art of "knot work" for such decorative and useful articles as women's belts and girdles, pulls for lamps, curtains, shades, hand bags, etc.

THE DOMESTIC INDUSTRY

History.—In 1824 the plaiting or braiding machine was first introduced from Germany, and in the succeeding year the Jacquard machine was brought over. Gold laces and braids were made by power in Philadelphia several years before the attempt was made in Europe, and the use of power for the making of fringe may be said to have been first adopted in Philadelphia. In 1860 there were in Philadelphia seven establishments engaged in the manufacture of cotton webbings, tapes, and braids, with an aggregate capital of $158,000, and turning out an annual product valued at $265,000. In 1867 an establishment in Philadelphia, founded in 1824, operated 130 coach-lace power looms, 100 narrow-ware looms, and 400 plaiting or braiding machines, this firm having purchased in 1857 the entire business of a Massachusetts company which at the time was the largest manufacturer of coach lace in America.

The great development of the domestic braiding industry has taken place within the past 30 to 40 years, and its present high efficiency is largely due to the perfection of the braiding machine by domestic machinery manufacturers who gained their knowledge of braiding in Germany, where the industry has employed high-grade mechanical talent for generations past. The founders of one large domestic machine plant, having at their start in 1892 the advantage of thorough familiarity with the German industry and a well-grounded experience in the machinists' trade, have developed the braiding machine to the highest state of perfection in mechanical detail, workmanship, and efficiency. As this includes all modern equipment, the domestic braiding industry, supplied with the very latest and improved machines, is capable of meeting any competition as to designs, styles, and types of fabrics. One of the largest domestic plants manufacturing practically every kind of braid that can be produced on a braiding machine is of modern construction and equipped with up-to-date domestic machinery; and although completed only within recent years is now being doubled in capacity and should prove the best equipped plant in the industry, whether at home or abroad.

Geographical distribution, organization, and equipment of the braiding industry are not separately shown, but are included with those of the cotton small-wares industry. The Census of Manufactures showed a total of 62,630 braiding machines in use in 1919 in the manufacture of cotton small wares. Of these, 13,333 were in Massachusetts, 1,498 in New Jersey, 5,957 in New York, 12,256 in Pennsylvania, 27,275 in Rhode Island, and 2,311 in all other States. In this equipment, 1,672,081 bobbin carriers were employed, averaging 26.7 to the braiding machine.

Materials used.—In the manufacture of cotton braids, the cotton yarns used may be single or ply; unbleached, bleached, or dyed; plain or mercerized, polished or prepared. India rubber strands also are used in the construction of elastic braids.

Methods of production.—While in ordinary weaving there are two sets of threads, the warp and the filling, in simple braiding only one

set is used. In braiding there may be strands or threads of different materials, sizes, and colors and, in elastic braids, strands of india rubber are fed in during the braiding.

In the process of braiding, the threads or strands may be plaited together in many ways, so that each thread or strand plaits with every other one according to the pattern adopted.

Braids are made round, flat, or tubular, according to the number and predetermined routes of the bobbin carriers. The threads or strands making up the article are wound upon bobbins, either singly or in pairs, and the ends are all carried to the center of the machine, where the interlacing of the threads is completed in a suspended eye or "former"; from this, the finished braid is continuously drawn off, as produced, by a take-up motion, and deposited in a receiving can. Some braids are wound on reels as completed.

Many articles are made by braiding over cores of different materials. In this manner electric cords are covered with insulating materials, packing materials are developed, and braided hose is made. Sometimes in covering cords with more than one ply, two or more braiding units are used tandem, being combined in the one machine.

Preparatory and finishing processes.—The necessary preliminary processes for the yarns and materials are similar to those employed in the production of small wares, and the same data as to bleaching, dyeing, and finishing, will hold for both weaving and braiding. Braids are sized and calendered and put up for the trade in rolls or packages of stated lengths, and are matched by sample cards, showing widths and arbitrary stock numbers for identification. Braids may be steamed and embossed for certain purposes.

Machinery.—The braiding machine of domestic manufacture has been highly developed in various types, from the simplest for the plaiting of single cords, to the complex, equipped with Jacquard motions, for the making of Barmen laces and braids of complicated designs. Domestic braiding machines are equal to any that can be imported, in regard to capacity, efficiency and perfection, and to workmanship and materials.

The fundamental parts of the braiding machine are the two horizontal plates, preferably of steel, connected by stay bolts with an intervening space of about 4 inches, the lower plate acting as the bed plate of the machine, and carrying the studs or gear bolts on which horn gears revolve. The horn gears are double-flanged gear wheels, carrying notches or horns in the upper flange, and their object is to give the bobbin carriers the essential zigzag semiannular movements.

The strands of materials or threads composing the braid are wound on bobbins. The bobbin carriers are arranged in two series, one running from right to left, the other from left to right, crossing each other in their serpentine courses. The threads of one series are thus alternately laid over and under those of the other.

Guide grooves are provided in the top plate of the machine, corresponding nearly with the pitch line of the gears. The small inside plates, or quoits, are secured to the square shoulders of the gear bolts. The bobbin carriers move in the guide grooves, the carrier being provided below the top plate with a driver or pin which engages with the horns or notches of the gears below. By means of these pins, in contact with the horn gears, the carriers are moved

along through the guide grooves, the pin remaining in the horn of one gear until the point of crossing is reached, where it is transmitted to the next gear and carried along to the next crossing. At least two gears are necessary to produce a braid.

The most important part of the mechanism of all braiding machines is the carrier or spindle, upon which four duties devolve: To carry the bobbin on which the thread is wound; to provide a uniform tension in the thread; to let off the thread evenly; and to stop the machine when a thread runs out or breaks. In order to economize space, carriers for vertical bobbins are generally used; these are again divided into two classes, those with the thread-tension weights inside, and those with the tension weights outside the bobbins. The carrier having the tension weight inside the square stand on which the bobbin rests is the one generally used.

With all types of braiders the number of horns or notches in the gears must be at least double the number of the carriers, as each carrier must meet an empty horn in passing from one gear to the other.

Another important element of the machine is the take-off mechanism, equipped with changeable gears for varying the rate of take-up, according to the texture of the fabric to be produced.

Braiding machines are operated at various speeds, depending upon the type and capacity of the machine and the fabric to be made.

Machines for small braids, such as soutache, laces, etc., are generally built with two, three, four, or more units or heads on all plates. For driving purposes, braiders are generally grouped symmetrically, and operated from a shaft which may be either motor or belt-driven.

The character of the different braids produced is governed by the manner of arranging the horn gears, by the number of horns or notches, and by the distribution of the carriers on the available notches. There are four general classes of machines for the making of as many types of braids, as follows:

(1) Machines for making flat braids: These machines have a number of horn gears arranged in a circle. In the race-way above the horn gears each carrier is propelled from one horn gear to the other in semicircles until it arrives at the end gear, on which it makes a full revolution and returns to the last point of intersection, moving now in the opposite direction while being carried back to the starting point. With each new horn gear, the carrier crosses its former course and the thread carried by it is laid alternately over and under those of the carriers moving in the opposite direction. Between each two carriers there must be an empty horn, as otherwise the carriers would collide. At each point of intersection a carrier meets an empty horn on the next gear which enables it to move in between two carriers running in the opposite direction. For this reason the end gears have an uneven, and the middle gears an even number of horns; thus, at the end, each carrier is put back for the space of one horn in the rotation, and therefore always meets an empty horn at the points of intersection.

In order to produce a full even edge in the braid, the end gears always have more horns than the middle gears. Generally, the end gears are made with 5 horns and the middle gears with 4. This arrangement produces what is called plain braid.

If the middle gears have 6 and the end gears 7 horns, each thread will pass alternately under and over 3 opposite threads and the resulting braid is known as the "hercules." If the middle gears have 2 and the end gears 3 horns, the thread will pass under and over only one of the opposite threads, producing what is known as the "diamond" or "basket" pattern. In order to produce a braid of regular appearance, each thread should alternately lie over and under an equal number of crossing threads, which will always be the case if the middle gears all have the same number of horns and if there are an even number of gears.

The smallest number of gears that can be used on a braiding machine is two, in which case the end gears only are used. These gears must always have an uneven number of horns, and the braids produced on machines of this class are made with an uneven number of threads and are called "soutaches." These, the simplest braids that can be made, are used largely in passementeries and in dress and military trimmings; some are elastic, and others are made of cotton for candle wicking.

Braiders operating with large numbers of carriers are sometimes provided with beaters, consisting of combs with steel prongs swinging in and out in the plane of the braid former; the points of the prongs beat the threads into the braid and facilitate the forming of a tight and even fabric. On large machines the beater motions are highly developed and more complicated, and are extensively used where the tension on the threads is insufficient to force each deposited pick into place.

Where warp threads are to be used, the gear bolts are hollow and warp guides are provided and fastened to the threaded ends of the bolts, level with the tops of the carriers; arrangements for the warp spools are made under the frame.

In addition to the straight and plain braids a great many fancy braids are produced on flat braiding machines. Rickracks, wave braids, and braids of other patterns can be made by using tension weights of graduated sizes in the different bobbin carriers. Braids of this type are also produced with loops, or eyes, on one or both sides, by means of loop attachments, which are operated by the carriers and serve alternately to present and withdraw a wire at the forming point of the braid, at one time forcing part of the threads up over the wire to form the loop, and then allowing the threads to pass under the retiring wire, these periods being properly timed in the operation of the machine. By means of such attachments many varieties in design can be produced.

By allowing some of the carriers to run empty, or by removing them entirely, and with the proper use of warp threads, braids with holes or open work are produced, which, when made of glazed yarns or artificial straw, are used extensively in hat forms. Fancy braids are also produced by the introduction of gimps as warp ends, purl-edge braids being made in this manner. Many fancy effects are thus produced by the application of the openwork principle and the use of gimp warp threads of a contrasting color or material. The tension weights, warp threads, and loop attachments are the three most important factors in producing fancy effects in braids on plain machines, and with almost no limit as to variety of patterns.

(2) Machines for making cords and tubular braids: These are made with several complete carrier courses crossing each other. The

carriers of one group do not braid with each other but only with those of the other group or groups, and move simultaneously with them around a common center of rotation, the carriers being so arranged in the different courses that they do not collide in crossing. While most cord machines have two courses, some are made with three or more courses for producing what are known as coral braids. The simplest equipment for braiding cords would contain four carriers. Round braiding machines are arranged in the same manner as the flat ones for producing the plain, diamond, or hercules patterns. The round-braid machines differ from the flat in having no end plates and no end gears with an uneven number of horns.

The appearance of a cord is influenced largely by the number of horn gears, especially when a coarse material is used. A cord made with four gears is therefore almost square in section, and the greater the number of gears the greater the number of sides of the polygon, approaching the circle. If a soft pliable thread is braided over a core, the resulting braid will conform to the shape of the core, as is the case in packings.

Tubular braids have the appearance of two flat braids, one above the other, and joined at the edges. Shoe and corset lacings are braided in this shape. Tubular braiding machines are also used in braiding over the forms of beads, acorns, and molds for tassels. Some spindle bandings and picture cords are produced on round braiding machines, and buggy whips are braided over in the same machines. Insulating materials are also braided on wires, etc., with this type of braider.

Braiding machines are also made which combine the possibilities of Types 1 and 2. They are called cord-edge braid machines, and are so arranged that the course of the carriers producing the flat braid traverses at one point the course of the carriers producing the cord, in such manner that the threads of both sections are firmly interbraided. The products of such braiders are used for binding the edges of garments, such as overcoats, jackets, and skirts. These machines are further provided with attachments for cutting half the threads forming the cord, in this manner forming a brush-edge braid. Some other products of this type of machine are known as loop-edge cords, square cords, diamond pattern cords, plain pattern tubular braids, square braids, loop braids, and fancy coral braids.

(3) Machines for making stripe braids: Machines of this type are made on the principle of joining together two or more sections of flat braids by letting all the carriers of two adjoining sections twist around each other on a plate of such construction that each carrier coming from the right will return in the same direction after crossing one or two of the carriers coming from the opposite direction. In such machines supplementary horn gears are used, and many combinations can be made by groupings of the gears and carriers in different ways, according to the pattern to be produced.

(4) Machines for making lace braids, such as "Barmen lace," contain several courses, so constructed that the carriers of two adjoining courses can pass from one to the other. This braiding from one course to another, however, does not occur continually, as with the stripe braid, but only at intervals and can be regulated according to the pattern; up to certain limits, lace braids can be made by automatic switching of the carriers, certain carriers being provided with collar attachments which throw certain switches, opening and clos-

ing them according to the predetermined routes of the carriers. In these simple lace braids the individual strands are generally made in the form of rickracks or waves, the border of the braids being generally straight to facilitate the sewing-on or attaching of the article in use.

This arrangement for producing lace braids by means of switches operated by the carriers themselves, while allowing for a great many variations, limits the possibilities of the machine to the production of short patterns. The capacity of the machine can be increased by the addition of a revolving pattern disc, operating through connecting parts the switches which regulate the routing of the carriers. The most highly developed machines are provided with Jacquard attachments which, acting in a manner similar to the weaving Jacquard head, greatly increase the range of the braider, making possible the braiding of innumerable patterns of laces.

Production and consumption.—The production of braids was not recorded separately prior to 1919. The census for that year itemized production as follows:

	Linear yards	Value
Braids:		
Flat—		
Woven and knitted	58,350,120	$901,874
Lace and braided lace	101,663,950	1,886,470
Round (including shoe and corset laces)	894,249,563	15,195,776
All other	65,627,056	1,333,504

The production of this portion of the domestic cotton small-wares industry in 1919 therefore totaled 1,119,890,689 linear yards, valued at $19,317,624.

For 1921 the census recorded a production of "Cotton small wares, braided" amounting to 1,995,202,285 linear yards (10,112,922 pounds) valued at $13,025,750. But no details were given as to the types of articles included therein. Preliminary figures for 1923 show a value of $14,659,205 for braided cotton small wares.

Imports of cotton braids amounted to 2,545,964 linear yards, valued at $33,832, in 1919; 15,549,611 linear yards, valued at $172,378, in 1921, and to $157,829 in 1923.

Imported cotton braids consist largely of the rickrack, wave, and serpentine types and are mainly for trimming. On the other hand, the Census production figures, quoted above, for the braided portion of the cotton small-wares industry, embrace "lace and braided lace" and shoe and corset laces, neither group being recorded with braids in import statistics.

EXPORTS

Exports are not recorded.

IMPORTS

Imports of braids were not separately shown prior to the act of 1913. Recorded imports are listed under the tariff classification—"Braids, loom woven and ornamented in the process of weaving, or made by

hand, or on any braid machine, knitting machine, or lace machine." Imports of the fancy braids known as "Barmen lace" are not included thereunder, but are recorded, without specific mention, with "laces."

Table 23 shows imports of cotton braids from October 4, 1913, to December 31, 1924.

TABLE 23.—*Cotton braids, loom-woven, and ornamented in the process of weaving, or made by hand, or on any braid machine, knitting machine, or lace machine—Imports for consumption—Revenue, 1914–1924.*[1]

Fiscal year (unless otherwise stated)	Quantity	Value	Duty collected	Unit value	Actual and computed ad valorem rate
	Yards				*Per cent*
1914 (Oct. 4, 1913, to June 30, 1914)		$297,985	$178,755		60.00
1915		254,923	152,954		60.00
1916		112,593	65,956		60.00
1917		23,305	13,984		60.00
1918		21,171	12,708		60.00
1918 (July 1 to Dec. 31)	80,770	1,966	1,180	$0.024	60.00
1919 (calendar year)	2,545,964	33,832	20,299	.013	60.00
1920 (calendar year)	5,685,819	168,194	100,916	.030	60.00
1921 (calendar year)	[2] 15,549,611	172,378	110,313	.011	63.99
1922 (Jan. 1 to Sept. 21)	[3] 37,611,280	291,886	175,850	.008	60.24
Total (3,275 days, act of 1913)		1,377,186	833,910		60.55
Annual average (act of 1913)		153,488	92,949		60.55
	Pounds				
1922 (Sept. 22 to Dec. 31)	20,675	63,519	57,167	3.164	90.00
1923 (calendar year)	85,859	157,839	142,065	1.838	90.00
1924 [4] (calendar year)	71,836	115,142	103,636	1.603	90.00

[1] Not separately recorded prior to the act of 1913.

[2] Includes 1,605,696 yards (96,572 pounds), valued at $30,941, containing cotton of 1⅛ inches or longer and paying, under the emergency tariff act, 7 cents a pound in addition to the regular duty of 60 per cent ad valorem.

[3] Includes [illegible] yards (10,153 pounds), valued at $14,946, subject to emergency tariff act surtax of 7 cents a pound.

[4] Preliminary figures.

TABLE 24.—*Total braids, loom-woven, and ornamented in the process of weaving, or made by hand or on any braid machine, knitting machine, or lace machine—Imports for consumption, 1914–1924.*[1]

[illegible]

The value of the imports in the nine months of the fiscal year 1914 covered by the act of 1913 was recorded as $297,925. Imports decreased sharply during the war period, largely because Germany had been the main source. After the war, imports again increased and in the calendar year 1922 were valued at $355,417. This increase was due partly to the anticipated higher duties under the act of 1922, and resulted in the partial overstocking of the domestic market. In 1923, with higher duties in effect, imports dropped to a value of $157,829. This decrease was due, partly, to the overstocked market, to the rise in German exchange, and to changes in fashion. Preliminary figures for 1924 show imports of $115,142.

In addition to Germany, the main source, there are small imports from Czechoslovakia, Austria, and England. Rickrack braids predominate in the imports.

Table 24, page 90, shows the value of imports, separately listed as to material, of all braids enumerated in paragraph 358 of the act of 1913, and in paragraph 1430 of the act of 1922.

Prior to the World War braids of cotton predominated in the import trade, but since the war the main item has been braids of artificial silk, cotton braids having fallen into second place.

COMPETITIVE CONDITIONS

In the early part of 1923, importers and jobbers stated that the market was then overstocked, partly because of large imports in advance of the present law. Several leading jobbers of notions, and the purchasing agents of some large systems of chain stores, then stated that they were purchasing their braids from domestic manufacturers, and were unable to import to advantage. On the other hand, a few large jobbers of imported and domestic products asserted that they were able to import several lines of braids in competition with domestic articles. Cotton braids of the standard types are made of medium yarns readily obtainable in the domestic market, and the question of competition between domestic braids and those imported depends largely upon costs in this country and abroad. With the present rate of duty, it would appear that domestic manufacturers, equipped for quantity production, can compete in the domestic market with imports, and that some modern plants are even able to export.

TARIFF HISTORY

In the act of 1883, paragraph 324, cotton braids were dutiable at 35 per cent ad valorem; in the act of 1890, paragraph 354, they were provided for at 35 cents per pound, but with a minimum ad valorem rate of 40 per cent; in the act of 1894, paragraph 263, at 45 per cent ad valorem. In these three acts they were grouped in Schedule I with other cotton small wares. In the act of 1897 cotton braids were included in the lace and embroidery paragraph of Schedule J, and braids of cotton or other vegetable fiber were provided for at 60 per cent ad valorem. The same arrangement and the same rate of duty were provided for braids in the act of 1909, Schedule J, paragraph 349. In the act of 1913 braids were grouped with lace, embroidery, etc., of any material, in paragraph 358 of the Sundries Schedule, where, under the more extended description of "braids,

Braids of cotton and other vegetable fiber and other materials, including such as are known as "Battenberg braids," "crown braids," "featherstitch braids," "featheredge braids," "guipure lace braids," "herringbone braids," "honiton braids," "linen bobbins," "novelty braids," "renaissance braids," "rickrack braids," "star braids," "wave braids," and by various other names, were held to be dutiable at 60 per cent advalorem under paragraph 339 of the act of 1897. (G. A. 5096, T. D. 23564 of 1902, *Hiller et al.* v. *United States*, 106 Fed. 73 of 1901, certiorari denied, 180 U. S. 639.)

Certain so-called featherstitch braids, produced by a process of weaving and not of braiding, commercially known as "braids," were held to be dutiable as such under paragraph 339, and not under paragraph 320 relating to bindings, tapes, etc. (*Von Baur* v. *United States*, 141 Fed. 439 of 1905.)

In the case of *Steinhardt* v. *United States* (121 Fed. 442 of 1903), the Circuit Court for the Southern District of New York, reversing a decision of the Board of General Appraisers, held that "narrow-woven tapes of cotton, used generally for covering seams of underwear and waists" were dutiable as bindings or tapes at 45 per cent under paragraph 320, tariff act of 1897, and not as braids at 60 per cent, paragraph 339. In that case the court reversed the board's decision on the strength of the definition given in the Standard Dictionary that a braid is a "narrow, flat tape or woven strip for binding the edges of fabrics or for ornamenting them." But in *United States* v. *Baruch* (223 U. S., 191 of 1912) the Supreme Court held that cotton featherstitch braids ranging variously from about one-fourth to one-half of an inch in width, loom-woven, of white and variously colored threads of cotton or other vegetable fiber, and ornamented with raised figures in various designs, some of which had plain and others scalloped or ribbed edges, were properly dutiable at 60 per cent as braids under paragraph 339 rather than as tapes or bindings at 45 per cent under paragraph 320. The court held that where a conflict which had existed under prior tariff acts as to the classification of such articles had been settled Congress would not be presumed, in enacting a new tariff, to renew the conflict by not adhearing to the commercial and tariff meaning of the terms as it had been settled.

Under the act of 1909, cotton braids, whether as ornaments or otherwise and irrespective of the use to which applied, were held to be dutiable as braids under the provisions of paragraph 349. (G. A. 7110, T. D. 31000 of 1910.)

Under the act of 1913, elastic braids in chief value of india rubber thread, which are recognized as a distinct article of commerce and bought and used as such by manufacturers of braids, were held, in the absence of proof to show that the terms "yarns," "threads," or "filaments" have a meaning in trade and commerce different from the ordinary meaning, to be properly dutiable under paragraph 358. (G. A. 7626, T. D. 34887 of 1914.)

Rickrack braids, ornamented in design, were held to be dutiable as "braids ornamented in the process of weaving." (Abstract 37956 of 1915.)

PREFACE.

This is one of a series of Tariff Information Surveys prepared by the United States Tariff Commission and transmitted to the Committee on Ways and Means. The series covers all of the articles and commodities provided for in the tariff act of October 3, 1913, and others not specifically provided for. It is arranged in the numerical order of paragraphs of that act.

In some cases two or more paragraphs have been combined in one pamphlet. In doing this, industrial relationship of the articles has been followed when possible. In those instances where a paragraph has been treated under a preceding paragraph of the tariff act, reference is made to this fact at the point where the paragraph appears in numerical order. Where one grade of an article is dutiable and another grade of the same article is on the free list, the article is discussed under the dutiable paragraph, which appears first in numerical order in the tariff act. In certain instances articles of close industrial relationship and which occur in separate paragraphs of the tariff act have been combined under one paragraph for convenience of discussion. Reference is made to this fact at the point where the commodities would naturally occur in numerical order.

The first pamphlet in the series is an "Introduction and Index," which contains:

1. An introductory chapter discussing the scope of the series and the general method of treatment.
2. An alphabetical index of the articles provided for in the tariff act of 1913, showing the paragraph of the act in which the article is provided for and, if discussed under a different paragraph, the number of such paragraph.
3. A list of the pamphlets in the series, showing the paragraphs and articles included in each pamphlet.

Thus by use of this "Introduction and index," the exact location of the discussion relating to a given article or commodity can be ascertained.

In the preparation of this report the Tariff Commission had the services of Evelina P. Kean, of the textile division of the commission's staff, and of others.

COTTON KNIT GOODS.

General Introduction.

The knit-goods industry in comparison with weaving is of recent development, its origin dating from the invention of the knitting "frame" in the latter part of the sixteenth century. In the three and a quarter centuries which have since elapsed great strides have been made in the application of the knitting process.[1] The knitted fabrics now produced vary from an extremely elastic type having a stretch several times the original width to a firmly knit texture with little more "give" than a woven cloth; and, from a plain fabric made throughout of one kind of yarn in a plain loop stitch to elaborate designs in color combinations or in stitch formation. A decided advantage of knitting over weaving is that garments can be shaped entirely on the knitting machine. This is of special importance where the material used is expensive and the elimination of material waste offsets greater labor cost, or where the garment made is so simple that its completion on the knitting machine requires less labor than would cutting and sewing, as, for example, the seamless stocking. In general, knitted fabrics can be produced at less cost than woven fabrics of similar material, because the rate of production is greater.

The value of knit goods produced in the United States increased from $95,833,692 in 1899 to $713,140,000 in 1919, and the number of establishments from 1,006 to 2,050. The increased use of cotton yarn in the knit-goods industry is shown in the table below:

Table 1.—*Cotton yarn used in the knit-goods industry in the United States.*

[From the Federal Census.]

	Purchased.	Made in knitting establishments.	Total.
1899—Pounds	131,820,068	40,845,889	172,665,957
Per cent	76.34	23.66	100
1904—Pounds	161,500,466	39,954,890	201,455,356
Per cent	80.17	19.83	100
1909—Pounds	216,987,611	69,171,277	286,158,888
Per cent	75.83	24.17	100
1914—Pounds	205,524,143	75,970,761	281,494,904
Per cent	73.01	26.99	100
1919—Pounds	217,411,343	87,063,037	304,474,380
Per cent	71.41	28.59	100

The industry has developed faster than the above figures indicate, because finer and finer counts of yarn are being made up into hosiery, underwear, and other knitted articles. Hence, the pounds of yarn consumed are not an exact index of the quantity of goods produced. The yarns used have improved in finish as well as in fineness. In 1914 only 15,672,427 pounds of mercerized yarn were consumed, compared with 30,519,234 pounds in 1919. A little over one-fourth of

[1] Dept. of Com. Misc. Series, No. 31, p. 173. Chamberlain and Quilter: Knitted Fabrics. Metcalf: Knitting.

the total yarn used was made in the knitting mills and less than 1 per cent was imported in 1914. Investigation showed that the bulk of the yarns imported for the use of the knit-goods industry in 1914 ranged from 50s to 99s.[2]

Cotton knit goods include knit fabric in the piece and all types of knit articles—hosiery, underwear, gloves, sweaters, bathing suits, towels, and fancy specialties; the bulk of the output, however, consists of hosiery and underwear, the value of which in 1919, totaled $297,184,505.

Although there are considerable quantities of knit cotton fabric in the piece, the Census Bureau does not record its production separately from knit fabric of other materials. Knit cotton gloves were recorded separately only in 1919. The production of hosiery and underwear knit of cotton is more important than that of silk or wool, and, in fact, is almost equivalent to the combined output of the two. According to the census, in 1899 cotton hosiery and cotton knit underwear combined represented 52.49 per cent of the value of the total output of the knit-goods industry in this country; in 1904 they amounted to 57.43 per cent; and in 1909, to 57.77 per cent. During the five years 1909 to 1914 the use of silk hosiery became so much more general that the recorded production of cotton knit goods declined in 1914 to 49.57 per cent of the total output of the knitting industry. The proportion was further reduced to 41.67 per cent in 1919. This was the result partly of an actual decrease in the quantity of cotton hosiery, but principally of the phenomenal growth of the outerwear industry, which uses more wool and silk than cotton. The great demand in the domestic market accounts for the large production in this country, as the share of the United States in export trade is normally very small.

The following table of international trade in cotton knit goods in 1913 shows the principal countries of export prior to the war, and the most important markets. Similar statistics are not available for a post-war year:

TABLE 2.—*International trade in cotton knit goods.*

[Calendar year 1913, except where noted.]

[a] Year ended Mar. 13, 1912. The figures include knit goods of all kinds.
[b] Year ended Mar. 31, 1913.
[c] Figures include knit goods of various fibers other than cotton.
[d] Year ended June 30, 1913.

[2] Tariff Information Series, No. 12.

The predominance of Germany in pre-war export trade in cotton knit goods is very evident from the above table. This position was entirely lost during the war, and to what extent it has been regained can only be judged from trade reports and the partial trade statistics that are available. It is said that the output of the German hosiery mills is about 60 to 80 per cent of the 1913 production.[3] Exports of cotton hosiery and underwear have apparently not reached the pre-war level, as 15,013,400 kilos[4] were exported in the calendar year 1913 and 5,815,300 kilos in the year ended April, 1922. The fact that 2,471,200 kilos, or more than one-third the total of the post-war year, were shipped in the four months January to April, 1922, might indicate that exports are on the increase, although it is pointed out by American consular agents that German manufacturers are not likely to retain any decided advantage over their foreign competitors.[5]

France, although far exceeded by Germany in the magnitude of her foreign trade in cotton knit goods, was second in 1913. Unlike other countries, France was too much involved in the war to be able to profit to any extent by Germany's enforced withdrawal from outside markets. French mills were, no doubt, kept busy supplying hosiery and underwear for the French armies. The total quantity of cotton knit goods exported from France amounted to 1,884,500 kilos in 1913, and to 1,900,800 kilos in 1921.

During the war when Germany was blockaded, the countries that were able to increase their production made every effort to supply the markets that had been users of German goods. The Japanese were quick to seize this opportunity, and enlarged their knit-goods industry as rapidly as possible, importing all the equipment they could obtain. Their goods were sold at so low a price that they were at first able to place enormous orders, but because of their limited knowledge of foreign requirements, their goods did not meet with great favor, and after the war Japanese exports fell off in volume.

British knit-goods manufacturers, who had hitherto been interested primarily in woolen goods, turned their attention to cotton. Their pre-war exports, in comparison with the exports of Germany, were insignificant, and in fact were much smaller than imports into Great Britain, which accounted for over one-third of the German foreign trade in knit goods in 1913.[6] The value of cotton knit goods exported from Great Britain in 1920 was about four times that exported in 1913, the greatest increase being in hosiery.

The growth of the American export trade in cotton knit goods was more extraordinary than that of any other country, increasing from a

value of $2,613,806 in 1913 to $54,458,062 in the calendar year 1920. The following table shows the markets in some detail:

Exports have always been scattered over a wide field. More than 100 markets therefor are listed in the Commerce and Navigation Reports. The great expansion in the export trade during the war represented not so much the acquisition of new markets as increased trade where some trade already existed. A considerable proportion of it was with Great Britain and in some years probably included large "war orders." The greatest total exports, however, were in 1920. In 1921 the value was less than one-fifth that in 1920. This was still much above the pre-war average value and, even allowing for increased prices, was probably larger in volume.

American exports of cotton knit goods increased relatively more than did production during the same period, notwithstanding diminished imports. The domestic market shows an increasing tendency toward the use of silk, which explains the surplus of cotton knit goods for export during a period of general prosperity and high wages.

Imports, which consist principally of hosiery, have never been a large part of the domestic consumption. The largest total value

of cotton knit goods imported in any one year since 1891 was $9,032,574, in 1908. This was less than 8 per cent of the 1909 production of cotton hosiery and underwear. Imports of cotton knit goods average about 10 per cent of total imports of cotton manufactures, and the average equivalent ad valorem rates on cotton knit goods have always been considerably higher than on total dutiable cotton manufactures; under the acts of 1897 and 1909 the rates were frequently even higher than the rates for laces and embroideries. Judging from the small proportion of imports, previous tariff rates have been a more or less effective barrier to foreign trade in cotton knit goods as a whole. Table 4 gives the total imports of cotton knit goods and the percentage received from each country. This shows clearly the predominance of German goods in the imports, and the rise and decline of Japanese trade in the 5-year period, 1917–1921. The total value of imports for 1921 was not far below that of 1914, the only pre-war year which included all cotton gloves,[7] but as the unit value of gloves, an important item, was over twice that of 1914, the volume of goods received was not as great.

COTTON HOSIERY.

SUMMARY.

The output of the American cotton-hosiery industry in 1919 amounted to 60,613,342 dozen pairs of socks and stockings, valued at $153,497,486, a decrease of 1.3 per cent in the quantity produced since 1914. This decrease was the outcome of the growing popularity of silk and artificial-silk hosiery. From 1899 to 1919 there was a quantitative increase of 130 per cent.

Duties on cotton hosiery from 1891 to 1920 averaged 60.61 per cent ad valorem. Imports have not been large in comparison with domestic production. In 1914 imports amounted to 3.6 per cent of the domestic production; in 1919 they were entirely negligible. The emergency tariff act, which placed a duty of 7 cents a pound on hosiery made of long-staple cotton, does not seem to have affected the character of the imports, because about one-half of the imports since that act became effective have been dutiable under that provision. This additional 7 cents a pound increased the equivalent ad valorem duty on the articles upon which it was imposed by about 4 to 5 per cent, and on the total cotton hosiery imports by about 2 per cent. Practically all of the cotton hosiery brought into the United States comes from Germany. In normal times that country supplies most of the cotton hosiery which enters into international trade.

The embargo which German trade suffered during the war left the usual foreign markets of Germany open to the cotton-hosiery industry of other countries. An extraordinarily rapid expansion of the American export trade took place during the years of industrial prosperity immediately following the war. In the fiscal year 1920 American manufacturers shipped abroad 12,392,935 dozen pairs of cotton hosiery, valued at $37,178,239. This was more than twice the quantity ever imported in a single year. Since 1920 exports have fallen off considerably. The general business depression, rather than competition, has been the cause. However, although Germany has not regained her former trade, it is noticeable that her exports to several western European countries have increased, while those of the United States to the same countries have dwindled. The question of competition for the American manufacturer seems to resolve itself into domestic competition in the domestic market and foreign competition in foreign markets. The tariff problem is overshadowed by the labor problem and the problem of trade facilities—transportation, credit, and exchange.

GENERAL INFORMATION.

TARIFF ACT OF OCTOBER 3, 1913.

PAR. 259. Stockings, hose and half hose, made on knitting machines or frames, composed of cotton or other vegetable fiber, and not otherwise specially provided for in this section, 20 per centum ad valorem.

PAR. 260. Stockings, hose and half hose, selvaged, fashioned, narrowed, or shaped wholly or in part by knitting machines or frames, or knit by hand, including such as are commercially known as seamless stockings, hose and half hose, and clocked stockings, hose and half hose, all of the above composed of cotton or other vegetable fiber, finished or unfinished; if valued at not more than 70 cents per dozen pairs, 30 per centum ad valorem; if valued at more than 70 cents, and not more than $1.20 per dozen pairs, 40 per centum ad valorem; if valued at more than $1.20 per dozen pairs, 50 per centum ad valorem.

DESCRIPTION.

There are three general classes of hosiery, according to method of manufacture: Full-fashioned, seamless, and "cut" hosiery.

Full-fashioned hosiery, which is made on flat knitting machines [1] of the Cotton type, is knitted flat, shaped, and selvaged ready for seaming. The full-fashion machine shapes the stocking in the knitting by increasing or diminishing the number of stitches in the width. The stitches in the width form lines of interlocking loops running the length of the stocking. These lines are called wales; each wale represents the work of a needle in the machine. To narrow the fabric the loop carried by one needle is transferred to the needle next it toward the center, so that where two wales were being knit only one will continue. This is done simultaneously on each side of the stocking, so that the finished article will show, along either side of the seam just above the ankle and at other places in the leg and foot, a series of what appear to be larger stitches but which upon examination prove to be the points where two or more wales become one. In this manner the full-fashioned stocking is made to conform closely to the shape of the leg.

Seamless stockings are made in tubular form on circular machines and because of the constant diameter of the machines can not be

[1] See Tariff Information Survey, Textile Machinery.

widened and narrowed as can full-fashioned stockings. Some slight difference is made by more tension in the ankle portion, but the shaping is almost wholly dependent upon the boarding process. In a seamless stocking the heel and toe are made in the form of pockets. The toe which is at one end of the open tube is closed after leaving the machine.

Because of the superiority of the full-fashioned hose it is desirable, for sales purposes, that the product of the circular machine shall resemble that of the flat machine as nearly as possible, hence an unnecessary seam is frequently put on these hose, which are then known as "mock seamed." Sometimes this is done by a separate operation on a power sewing machine, just as the actual seam is made in full fashioned hosiery, but a knitting machine has been developed which will simulate a seam during the process of knitting. This similarity in appearance to full-fashioned hosiery has been carried still further on a recent development of the circular machine by the formation of stitches called "crow's feet," which look like the narrowing stitches in full fashioned hose, but which do not in reality alter the number of wales. Such stockings are usually called "mock-fashioned" or "fashion-marked."

Full-fashioned hosiery fits better and is more elastic than seamless hosiery; but seamless hose are cheaper, as the circular machine is more productive and the labor cost therefore less. Comparatively unskilled labor can be used to operate a circular hosiery machine—in fact, this work is frequently done by girls—whereas the operator of a full-fashion machine is always a man, and usually a skilled mechanic.

The labor cost in the manufacture of full-fashioned hosiery is usually a greater proportion of the total cost than in the manufacture of seamless hosiery. The knitting is slower, the knitters receive a higher wage, and the operatives in subsequent processes are usually better paid. Manufacturers of full-fashioned hosiery estimate the labor cost at from 33⅓ to 60 per cent of the total cost, while the seamless ranges from 25 to 50 per cent. A slight difference in the method of making a stocking will give a difference in labor costs, and the possibilities for variation are so endless that it is impossible to lay down any hard and fast limits of the proportion of labor cost.

Seamless fashioned hosiery can be made on a type of straight knitting machine which has two parallel rows of needles. This machine has one advantage over the ordinary circular machine—the hose can be narrowed to the shape of the ankle without seaming, but it is not extensively used because production is slow, as the machine is not entirely automatic. A variation of the circular machine, which can produce seamless fashioned hosiery, is used by one or two concerns, but this machine is not on the open market.

"Cut" hosiery (par. 259, act of 1913) is an inferior grade of hosiery cut out (as a seamstress would cut a dress) of long tubular webs made on large circular machines or from the good portions of other kinds of materials spoiled in the making. Very little of this is done in the United States at the present time, and the salvaging of imperfect hose is probably the only reason for its continuance. The Germans have developed a type of children's sock which has a cut foot and a selvaged top. The top is made separately on flat machines, which makes possible elaborate Jacquard designs and color combinations. To lessen the price of the article, this top is combined with the cut foot or, in some cases, a seamless foot.

Some mills that have spinning departments reduce the material in hose which are too imperfect to sell as seconds to the condition of raw stock, and then spin it into coarse yarn, from which they make heavy socks, known as lumbermen's or workmen's socks. The yarns in some rejected goods can be reclaimed by raveling and rewinding.

Competing articles.—Fastidiousness in matters of dress has become so marked that an expensive article appealing to taste is strongly competitive with one more durable but less attractive. Matters of general style in dress, such as the length of women's skirts, have a marked effect upon the character of hosiery demanded. Of late years silks and artificial silks have gained such universal vogue that the cotton-hosiery industry has felt the encroachment of these lines. In fact, relatively small quantities of full-fashioned cotton hosiery are being made. On the other hand, many manufacturers of seamless hosiery who at one time produced cotton hose exclusively, are making stockings of silk and artificial silk. This trend is emphasized by the alignment of census figures showing the increase in the silk-hosiery industry to have been nearly 2,000 per cent and in cotton only about 7 per cent in 1914 over 1909. Silks and artificial silks increased 120.8 per cent in 1919 over 1914, while there was a reduction in the cotton-hosiery output.

The figures given above represent the relative growth and not the relative importance of the two lines of manufacture, the actual quantity of cotton hose having always been much greater than that of silk. The total production of silk and artificial-silk hosiery amounted in 1914 (in quantity) to about 14 per cent of the total production of cotton hosiery. In 1919 it had increased to 31 per cent.

DOMESTIC PRODUCTION.

Size of the industry.—It is impossible to give any definite idea of the size of the cotton-hosiery industry except through production figures, as it is not separated from other types of hosiery. The American Directory of the Knitting Trade for 1920 lists 727 manufacturers of seamless hosiery, who are probably predominantly cotton manufacturers, and 106 makers of full-fashioned hosiery, the greater number of whom probably do not make cotton hose. The value of the output of the hosiery industry in 1919 represented about 43 per cent of the total knit-goods industry, and cotton hosiery about 50 per cent of the total hosiery industry. In 1909 the value of cotton hosiery produced was over 81 per cent of the total hosiery produced.

Materials.[2]—Cotton yarn from which hosiery is made covers a wide range of counts and processes. Number or count of yarn means the number of 840-yard hanks required to weigh 1 pound. No. 1 cotton yarn measures 840 yards to the pound and No. 100 cotton yarn measures 84,000 yards to the pound; the higher the count the finer the yarn. The yarns most used in hosiery range from 16s to 20s in coarse goods and from 80s up to 120s in fine goods.

One of the processes preliminary to spinning is carding; ordinary yarn which undergoes no special additional process is usually called "carded" yarn. Sometimes the cotton is combed as well as carded before it is spun. Yarns so made are described as "combed." They

[2] See Tariff Information Series, No. 12, and Summary of Tariff Information, 1921, p 843.

are smoother and stronger than carded yarns made from similar cotton but are relatively more expensive, not only because of the extra labor, but also because of the greater amount of waste. A further removal of fuzz and loose projecting fibers is effected by gassing or singeing after spinning and doubling. This greatly improves the appearance of the yarn, making it smoother, rounder, and brighter and incidentally slightly increases the strength.

Mercerization is a process in which the yarn is treated, under tension, with caustic alkali to obtain a lustrous silklike finish. Accompanying results are greater strength and greater affinity for dyestuffs. Mercerized yarns are frequently also gassed.

Lisle yarn refers to a fully gassed two-ply yarn, the individual threads are spun with a right and left twist, respectively, and then doubled. This gives the yarn the hard, clean, wiry appearance of linen.

The condition and finish of the yarn used in making hosiery materially influence the price and are therefore frequently included in descriptions for price quotations.

The manufacture of hosiery is in many cases a highly integrated industry. Large mills frequently spin the yarn for their standard grades, buying only that which is required in small quantities. Such mills are more independent than those which rely solely on purchasing, but at the present time are more liable to losses on a receding market as their raw material is farther removed from their finished product.

Knitting yarns are sold on the open market in greater quantities than weaving yarns because the latter are more frequently made in the establishments in which they are used. Philadelphia is an important center of the knitting-yarn trade.

There are no separate statistics showing the amount of cotton yarn used in making hosiery, but the total quantity of cotton yarn used in the knit-goods industry is shown on page 1. It is practically all of domestic origin.

Long-staple cottons, of which the imported Egyptian, American-Egyptian, and southern peeler are the most important, make the best hosiery yarns. Sea Island cotton is of the highest quality, but very little is obtainable since the boll weevil has infested the region in which it is grown.

Equipment.—Many machines used in the hosiery industry are made in this country. The full-fashion hosiery machine of the Cotton patent type, though originally an English invention, has been developed commercially in Germany. Most of the full-fashion machines in use in the United States are of German manufacture. However, they are now being built in this country. These machines are so large and intricate that their construction is necessarily slow, and at the time of greatest expansion in the hosiery industry they could not be turned out fast enough to meet the demand. There has been little modification in this type of machine for some years; loss through obsolescence has therefore been almost negligible. The trend of the trade toward finer hosiery has necessitated the substitution of finer-gauge machines—many mills have replaced 33 and 36 gauge machines by 39 and 42 gauge—but the machines so replaced have been disposed of to manufacturers of coarser goods. One improvement developed in this country is the individual-motor drive, which

requires less space and saves time, because the stoppage of one machine does not arrest the motion of others, as in the belt and shaft system.

The seamless industry presents quite a different situation. The latest circular machines are so perfectly automatic that only the closing of the toe is needed to complete the formation of the stocking after it is knit. But this perfection has been brought about by a series of improvements which in many cases have called for the actual scrapping of antedating machinery. The result is that whereas seamless hosiery machinery is more nearly automatic than the full-fashioned, the industry has not kept pace with the inventions, and many mills, even some of the largest, are using machines which are really out of date. This is partly because of the capital required to replace the machinery, but very largely because the growth of the industry has so taxed the machine manufacturers that it has been impossible to obtain the machines at any price.

Besides the knitting machines, an essential machine in either the full-fashioned or the seamless industry is the looper, which is used in closing the toe of a seamless stocking and both the heel and toe of a full-fashioned. These machines are made in Germany and in the United States. Most manufacturers prefer the American model, as it is simpler in construction and easier to keep in good condition.

Hosiery mills are usually equipped with their own dyeing plants, the machinery for which, including boilers and hydro-extractors, requires the investment of considerable capital. The stockings are given final shape by boarding, a process which requires special equipment. One method uses thin, shaped, wooden boards over which the hosiery in a damp condition is stretched. A large oven or drier, in which the covered boards are stacked, is necessary. Some mills are equipped with hollow metal forms fastened upright along a table. Superheated steam passing through the forms dries the hosiery. One elaborate type of boarding machine is practically automatic; it strips the hose and lays them in piles of a given number.

Methods of production.—In most mills the product is standardized, each mill making only a limited number of styles in various grades and sizes. (Women's hose are usually made in sizes 8½ to 10. One mill which exports to the Orient makes sizes as small as 7.) The standard colors are black, white, and various shades of brown to match the prevailing color in shoes. Other colors are usually made only on special order. Fancy hose with clocking, embroidery, or openwork varies with the dictates of fashion but forms a small proportion of the entire trade.

Practically all machinery used in the hosiery industry is power driven. Most of the processes are mechanical, although handwork is still employed to some extent.

In the manufacture of full-fashioned hosiery the operation of two machines and an intermediary process of transferring are required for the actual knitting. The first machine knits the leg, the second the foot of the stocking. The legger is a long machine usually having 18 sections, on which 18 legs are knit simultaneously. The machine is set so as automatically to narrow the fabric by transferring two loops to a single needle at desired intervals. When the legs are finished, they are transferred to the footer, which has about 20 spaces. As it takes less time to complete the foot, three leggers are

26546—23—I-6——3

generally employed to one footer. The four machines, known as a "set," will produce about 180 dozen pairs of stockings a week. After the completion of the knitting the material is a shaped, selvaged piece, which is made into a stocking by seaming down the back of the leg and along the sole of the foot. The toe and heel are closed by "looping." This is done on a machine which produces a very flat join by stitching together a single loop at a time from each side of the seam.

For seamless hosiery the entire stocking is usually knit on one circular machine. Where ribbing is desired, the ribbed portion is knit on a machine of slightly smaller diameter than that which makes the plain. This gives greater elasticity to the ribbing. A machine can be used which will knit both the ribbed and the plain portions of the sock or stocking, but the product is not so satisfactory.

Except on the latest automatic machines the hems or welts of women's seamless hose must be turned by hand and sewed on power-sewing machines. Both the circular and the flat machines are built with different numbers of yarn changes. When a machine has several yarn changes, different kinds of yarn may be introduced into different parts of the stocking. This permits the use of cheap heavy yarns where the strain is great, and of fine yarn where the appearance of the stocking requires it.[3] When split-foot or double-soled socks or stockings are made, extra yarn is introduced. This is knit into the sole, but not into the upper part of the foot. As there is no provision in a circular machine for the yarn to be cut after each course, a web of loose threads on the inside of a split-foot seamless stocking must be cut out. In some mills this is done on a small upright machine over which the hose is slipped. The operative presses a lever and both ends of the thread are clipped at once. Where these machines are not used the threads are clipped by hand with shears.

Clocking, ornamental work on the ankle or side of a stocking, may be worked in the hose during the process of knitting by plating or in an openwork design, or it may be embroidered by hand or machine after the stocking is knit.

Plating is knitting with two yarns simultaneously, one yarn appearing on the face of the fabric and one on the reverse. A design may be achieved by using different materials or contrasting colors.

Besides the knitting there are many other operations on both full-fashioned and seamless hosiery—looping, turning, dyeing, boarding, pressing, inspecting, mending, stamping, labeling, and boxing—which necessitate the handling of the article many times.

Comparison of American and foreign processes.—The development of the hosiery industry in foreign countries has been almost entirely in the full-fashioned lines, the seamless industry receiving little attention until the shortage of German goods caused manufacturers in many countries, notably Japan, to become interested in rapid production and to import greater numbers of American circular hosiery machines.[3] Some circular hosiery machines are made in Germany, England, and France.

The same kinds of full-fashion machines are used in the United States as in other countries, and the processes are practically identical.

The method of making full-fashioned stockings in America is known as the French system. This is generally used on the Continent

[3] Dept. of Com. Misc. Series, No. 31, p. 182.

of Europe. The English system is somewhat different. It requires only one machine on which the sole is knit as a continuation of the upper part of the foot. The completed stocking has a seam down the back of the leg and a seam along each side of the foot instead of along the sole. There is no join at the toe. This process involves no transferring, but the seaming is more complicated.

Organization.—There is less homogeneity in the organization of the hosiery industry than in most industries of equal importance, inasmuch as large corporations constitute a smaller percentage of the total establishments. This is especially true of the seamless-hosiery industry where, because of the relative cheapness of the machinery, the simplicity of the operations, and the small space required for housing the equipment, a small mill can be operated at a profit. On the other hand, the degree of standardization in the industry, the possibility of quantity production, and the enormous market for cotton hosiery make the industry eminently adaptable to large scale operations. The full-fashioned industry requires the investment of more capital because of the greater cost of the machinery and the more careful finishing processes necessary on a superior grade of goods. Census figures for capital invested or equipment are not given in detail for the hosiery industry, but the statistics for knit goods as a whole bear out the above statements.

In 1914 there were 1,662 knit-goods establishments having a capitalization of $215,826,340; in 1919 there were 2,050 establishments with invested capital aggregating $516,457,991. In 1914 and 1919, respectively, the number of establishments owned by individuals was 519 and 564; by corporations, 785 and 1,096; owned otherwise, 318 and 390, respectively. Of the total output the value produced in establishments owned by individuals was 9 per cent in 1914 and 7 per cent in 1919; in establishments owned by corporations, 80.5 and 83 per cent; in establishments otherwise owned, 10.5 per cent and 10 per cent in 1914 and 1919, respectively. There is evidently a tendency in the knit-goods industry, as in most others, toward concentration in corporations. In 1909 only 71 per cent of the total output was that of corporations.

Where cotton hosiery is manufactured on a large scale, the industry has become highly integrated, every process from spinning the yarn to dyeing and finishing being done in the mill.

Considerable variety of material is used in some mills—cotton, silk, artificial silk, and to some extent, wool hosiery are frequently all made by the same establishment, but the type of product varies little. The following table shows that practically the entire output of cotton hosiery is by mills engaged primarily in the manufacture of hosiery:

TABLE 2.—*Production of cotton hosiery, by type of establishment.*

Made in—	Quantity.	Per cent of total of quantity.	Value.	Per cent of total of value.
	Dozen pairs.			
Hosiery mills	60,200,033	99.32	$152,283,092	99.21
Underwear mills	355,708	.58	969,485	.63
Fancy knit-goods mills	57,582	.10	244,883	.16
Knitted-cloth mills	19	.....	26	.....
Total	60,613,342	100.00	153,497,486	100.00

Hosiery knitting machines can not well be used for any thing hosiery. For this reason hosiery is a more or less specialized ind try. This is less true of silk hosiery which is sometimes made fr fabric knit in the piece.

Geographical distribution.—The hosiery industry, especially cotton-hosiery industry, is not localized. In practically every St east of the Mississippi, and in many States west thereof, there several hosiery mills. Pennsylvania holds first rank in quanti and value of the hosiery produced, but there has been a very notic able change from cotton to silk in that State. The production cotton hosiery in 1919 was smaller by almost 10,000,000 dozen pai than the production in 1909. Reading is the principal center of t cotton-hosiery industry, although small mills are scattered all ov the State. North Carolina, with an ever-increasing production, second in quantity, though exceeded by Tennessee in value of outpu Durham is one of the principal manufacturing centers in the forme State, and Chattanooga in the latter. Generally speaking, cheape grades of goods are made in the South than in the North, but som large mills in the South make the finest grades of seamless hosiery o the market, and recently the manufacture of full-fashioned hosier has been begun. There are distinctive economic reasons for thi condition. In the first place, the industry is much newer in the South. In one respect this is an advantage, as newly constructed mills can be equipped with the latest types of machinery. Circular machinery goes out of date rapidly, and northern mills have frequently made their replacements with full-fashioned machines. In the second place, labor conditions make it possible to produce cheap grades of hosiery which have become unprofitable in the North. Labor in the South is less well organized, and wages are lower than in the North. Hours of labor are longer, and overhead expense is therefore reduced.

What has been said of the South is to some extent true of the Northwest. The trend, however, is toward the manufacture of better grades of goods in the South, in hosiery as in other textiles. Mills in the Southeastern States are usually supplied with electricity generated by the abundant water power.

Relation of domestic production to consumption.—In 1919 production of cotton hosiery amounted to 60,613,342 dozen pairs; imports were 60,686 dozen pairs; exports, 7,454,203 dozen pairs. Domestic consumption was therefore equivalent to about 53,225,000 dozen pairs in that year. By similar calculation consumption in 1914 was about 63,000,000 dozen pairs. It is significant that the decrease in consumption was during a period when there were practically no imports (see pages 24 and 25), which shows that it was due to change in the character of demand, and not to foreign competition. Domestic manufacturers have ample capacity to supply the home demand and then have a surplus, as is shown by the enormous quantities exported during the last few years. (See page 31.) There is, in fact, great danger of overexpansion and overproduction in the industry.

Domestic exports.—American manufacturers of cotton hosiery have acquired a remarkable export trade in the last six years. Exports of cotton hosiery were not recorded separately prior to 1918 but in 1914 the exports of all cotton knit goods, including underwear,

hosiery, and miscellaneous articles, were valued at only $2,546,822, which was above the average for the preceding 6 years. In 1918 cotton hosiery alone amounted to $11,578,209, in 1919, $20,837,032; and in 1920, to $37,178,239. The large values were partly the result of higher prices, but the quantities, which are more indicative of the volume of trade, show that the United States was one of the foremost countries in foreign trade during those years. The markets acquired by domestic manufacturers are widely distributed; in fact, over 100 countries are listed in Commerce and Navigation Reports as receiving cotton hosiery from the United States. One mill, which has foreign representatives, has a large export business, making small sizes especially for the oriental, chiefly Indian, trade. Some American mills have their own sales offices which handle foreign trade; others sell through jobbers. Inquiries in the trade developed the fact that exports are largely of seamless hosiery.

The prime cause for this newly stimulated trade was, of course, the removal of Germany from the field of competition. Other factors have entered into the situation. The generally higher standard of living the world over has created a larger demand for hosiery. More direct shipping facilities have been provided between the United States and many foreign countries. Improved banking methods allow American manufacturers to extend more liberal credits, and the new contacts which the country at large has formed with foreign markets have been a benefit to hosiery manufacturers. The drop in exports for 1921 might at first glance seem to indicate that the export trade was somewhat transitory and that probably all foreign markets would soon be reabsorbed by German interests. There are, however, other causes for this falling off of exports. The general financial depression the world over has seriously reduced the buying power of most nations. Argentina and Cuba, with whom this country carried on a large trade, have both suffered financial embarrassments. Argentina received large stocks of American goods in 1920, which could not be absorbed, and consequently further orders were postponed. The same was, to a lesser degree, true of Cuba, and the moratorium which was declared in the fall of 1920 retarded trade for several months. Practically the only markets in which German competition seems to have been effective since the war have been neutral countries of western Europe whose exchange has suffered little or no depreciation—Sweden, the Netherlands, and Denmark.

FOREIGN PRODUCTION.

Germany.—Chemnitz, in Saxony, is the center of the German cotton-hosiery industry. The German industry is almost entirely in the full-fashioned line, with some of the cut-foot type of infants' socks previously mentioned. Prior to the war German labor costs were so low that they could compete even with the American seamless hose in foreign markets. The seamless hose is a less acceptable article and would have to undersell the full-fashioned to hold the trade. No accurate statistics of the output of the German industry are available, and reports as to present conditions are conflicting. Without a doubt the Germans have made a strong effort to regain their export markets, and they have had no little success, but the industry faces many difficulties. Wages, it is true, are very low in comparison

with American standards, and in terms of American money ar
low in comparison with pre-war German standards. But they c
from day to day; in fact, wage agreements are commonly ma
only one month. The unions have succeeded in maintainin
enforcement of an 8-hour day, regulations regarding the numb
machines worked, and other restrictions which operate to some
advantage to the manufacturer. "The growing tightness of m
and the rising rate for private discounts, together with the
conservative attitude of the banks toward industrial loans is and
unfavorable factor in the manufacturer's balance sheet."[4] T
are high, with special export taxes levied on all goods sent out of
country. The mills are not greatly handicapped by shortage of
and coke, because Chemnitz is fairly well supplied with electric pow
though on the whole there is less electrification of industry in Germa
than in the United States. It is a fact that the Germans are now a
to sell their hosiery at prices below those possible to the Americ
manufacturer, but it is a problem how long this condition can contin
as the stabilization of the mark, even at a much depreciated leve
would tend to bring about a readjustment of wages which would forc
German prices nearer to the American. The following table show
the comparison of pre-war and post-war exports from Germany ex
pressed in weight. They are therefore not comparable with American
figures.

TABLE 3.—*German exports of cotton hosiery.*

[1] No statistics available for first four months of 1921.
[2] Austria-Hungary.

Some idea of the quantity in dozens may be gained when we consider that the weights of cotton hosiery run from about one-half pound a dozen for infants' socks to about 3 pounds for children's heavy ribbed hose. Imports under the emergency tariff act show an average in one period of slightly less than a pound per dozen, and in another period of slightly more than a pound per dozen. It is well known that these imports have been largely of infants' socks, and the average would probably be of lighter weight than the average

[4] Supplement to Commerce Reports. Trade Information Bulletin No. 48.

of the total German exports. The total exports from Germany in 1913, according to this calculation, would probably not have been much greater than the exports from the United States in 1920. It may be seen from this table that exports for the year ended April, 1922, were less than half those for the year ended December, 1913. In certain western European markets, as pointed out above, post-war exports were greater than pre-war exports.

France.—The French hosiery industry is of some importance and has been especially developed in fine goods. The average unit values of cotton hosiery imported into the United States from France are greater than from other countries. (See Table 6, p. 24.) Hosiery machinery is built in France, and special stress is there laid upon improvements which will result in higher quality of goods rather than in speed of production. Exports of hosiery are not separately stated in French statistics, but the weight of cotton knit wearing apparel exported from France was somewhat less in 1921 than in 1913; in fact, only in 1920 was there an important increase. French foreign trade in hosiery is probably greater than the British but far less than the German.

England.—Hosiery produced in the United Kingdom is more largely wool than cotton, but that the production of cotton hosiery has increased in several years is reflected by export figures as follows:

Calendar year:	Dozen pairs.
1913	721,967
1918	1,000,619
1919	1,513,379
1920	1,739,109
1921	489,394

The quantity exported in 1920 was less than one-sixth the quantity exported by the United States during the same period. Very little of the British goods was sent to South American countries, the bulk going to British possessions; American exports to these possessions, however, were in almost every instance greater than British.

Japan.—In the Japanese industrial movement the Japanese manufacturers naturally turned first to the simplest lines of manufacture. Thus American circular hosiery machines found a market in the Far East. This line offered a ready means of development when after 1914 German goods were difficult or impossible to obtain. American manufacturers of circular machines could not supply the machines desired by this trade during the last few years. Inquiries were also made by Japanese manufacturers for American full-fashion machines, but as late as August, 1920, none had been sold to that country, as the builders could not supply the domestic demand. It is probable that Japan is receiving German machines, as the machine manufacturers not being so seriously handicapped by lack of raw material, would profit by exporting at current rates of exchange.

The Japanese hosiery industry has not shown the same growth since 1914 as have other lines of knit goods, notably underwear. Considerable quantities of Japanese hosiery were exported, but the industry was soon affected by the depression in world trade. The majority of the hosiery manufacturers who started business during the period of war boom closed down in 1921.[5] The Japanese have

[5] British Board of Trade Journal, June 23, 1921, p. 710.

made a special effort to secure the trade of British India, and it is possible that they may succeed in that market to the exclusion of American and British goods. The quality of Japanese hosiery is so inferior that they have failed to gain a foothold in the American market and probably will not offer serious competition in many foreign markets. However, the Japanese Government by a rigid system of inspection is endeavoring to raise the standard of exports in this as in many other lines.

IMPORTS.

A comparison of import statistics with domestic production discloses extraordinary divergence. In the census years 1899, 1904, 1909, and 1914, cotton hosiery imports equaled 13, 10, 9, and 4 per cent, respectively, showing a steady decrease in the proportion of imports to production. Imports in 1919 were too small for comparison. There was an actual increase in imports from one-half decade to the next until 1909, but the imports did not keep pace with consumption, as is evinced by the diminishing ratios of imports to production. American mills turned out 61,409,575 dozen pairs of cotton hose and half hose in 1914, while imports for consumption totaled only 2,194,371 dozen pairs. The greatest quantity imported since 1891 was 5,921,503 dozen pairs in 1895, a low-tariff year, but this was probably swelled by holdovers in anticipation of a tariff reduction, as the figures for 1894 are much smaller than for the two preceding years. Impending tariff legislation with the probability of an upward revision would naturally have stimulated imports in 1921 and the first part of 1922. (See Tables 7 to 11, inclusive, pages 25 to 30.)

Imports by countries (Table 6, page 24), first stated by quantity in 1911, show that Germany was by far the most important source of foreign cotton hosiery coming into the United States, supplying 99 per cent in each of the first three years, 1911, 1912, and 1913; 98 per cent in 1914; 96 per cent in 1915; and as much as 68 per cent even in 1916. Subsequent imports from Germany were practically nothing until 1921 when they were again 96 per cent of the total.

English and French imports, according to their invoiced value, are of superior quality. For the years 1911 to 1914 the average unit value of German imports was $1.27 per dozen pairs, while the English was $2.78 per dozen pairs and the French $3.93. Japanese imports had an average value of 55 cents per dozen pairs in 1918, the only year in which any quantity came to this country. Unit values for the first quarter of 1922 were 96 cents for German goods, $5.47 for British, and $8.86 for French.

In order to obtain data in regard to the character of cotton hosiery imported the Tariff Commission sent an inquiry (August, 1922) to the appraiser at the port of New York, from whom it was learned that a smaller variety of cotton hosiery is imported now than before the war, largely because yarns are not available. Children's socks are now estimated to be about 10 to 15 per cent of the total imports; approximately 90 per cent of the children's socks are full-fashioned and 10 per cent cut with sewed feet. The cut socks have a selvaged

top knitted on a flat machine. Very little seamless hosiery is imported as it can not compete with the high efficiency in the manufacture and great output of the domestic article. It is estimated that 80 per cent are lisle and 20 per cent cotton. The usual gauges imported are 33, 36, 39, and 42. Extremes of price range were said to be difficult to quote because of varying conditions. They were estimated as follows:

	Value per dozen pairs.
Infants' cut hose	$0.55–$0.75
Infants' seamless hose	.90– 1.00
Infants' full-fashioned hose	1.10– 1.30
Infants' full-fashioned mercerized lisle socks	1.50– 1.75
Men's lisle half-hose	2.50– 3.25
Women's lisle hose	3.50– 5.00

Prices given are for usual grades; novelties and fancy goods would be higher.

Attention is called to the statement of the appraiser that as no statistics are compiled by his office the information given is largely estimated. It has been sustained by the largest importers of cotton hose at New York.

PRICES.

Grades of cotton hosiery are determined by so many elements—the quality of the yarn, the type of machine, the fineness of the mesh resulting from the gauge or number of needles, the method of reinforcing, the dyeing and finishing—that it is difficult to quote representative prices. In normal times hosiery prices undergo very little fluctuation, as the goods are scaled to sell at definite and unchanging retail prices—25 cents a pair, 35 cents a pair or three for a dollar, and so on. These levels could not be retained with the rise in costs of materials and labor. Once a radical departure from the old price standards had been made the element of speculation entered. This had the effect not only of increasing prices but of upsetting all price relations. It not infrequently happened that a low-grade hose commanded an equivalent or better price than a superior article.

The prices quoted in the War Industries Board bulletin (see page 73) are on popular-priced hosiery. Women's 33 gauge are about the coarsest full-fashioned hose made, and presumably would have sold for about 25 cents retail prior to 1914. Men's 176-needle hose, which are seamless, were made to sell for 10 cents a pair retail. Peak prices are not shown in this bulletin, as they were not reached until 1919 and the early part of 1920 when they soared to three or four times pre-war altitudes. Men's 176-needle hose were quoted at $2.50 per dozen pairs in July, 1920; six months later some were on the market for $1.

There has been a decided recession since 1920, but prices are still above the pre-war level.

The following extract from the Daily News Record of May 26, 1921, gives an idea of price trend during the last few years:

A decrease of 51 per cent in the cost of hosiery to the retailer as compared to the peak prices of 1920 is shown in a comparison of prices made available through reference to lists issued by the Durham Hosiery Mills. It was explained that the construction of some numbers had varied somewhat since pre-war times, but that the values are similar. The peak prices are those at which merchandise moved freely.

Between May 31, 1914, and May 31, 1920, the increase was 227 per cent, and the decline since 1920 is 51 per cent. These prices are the jobbers' prices to the retailers. The following prices indicate increases and decreases in price:

Name.	Price May 31, 1914.	Price May 31, 1920.	Per cent increase.	Price May, 1921.	Per cent increase since 1914.	Per cent decline since 1920.	Price July, 1922.[1]

[1] Furnished by the mill.

TARIFF HISTORY.

The tariff act of 1883 levied a flat rate of 40 per cent on all cotton hosiery other than "cut" hosiery. This was modified under the act of 1890 by breaking up the paragraph into value classifications dutiable at graded compound rates. The actual duties collected under this act averaged over 68 per cent of the invoice value. From 1891 to 1913 the rates on cotton hosiery were higher than on cotton goods in general. Though changes in classification and rates were made, the same system was adhered to. While the act of 1897 was in force larger quantities of cheap grades of hosiery were imported; this was counteracted in the act of 1909 by a raise in rates on the three classifications valued at less than $2 per dozen. Imports under the act of 1909 decreased. In 1908, 5,068,004 dozen pairs were imported; in 1913, only 2,028,988 dozen pairs.

The act of 1913 simplified that part of the schedule relating to hosiery by reducing the number of classifications from seven to four and by changing from a compound rate to an ad valorem rate only, ranging from 20 to 50 per cent. (See pages 32 and 33.)

The emergency tariff act of May 27, 1921, placed a compensatory duty of 7 cents a pound on all goods containing cotton with a staple of 1⅛ inches or over. This affected more than 50 per cent of the cotton hosiery imported in the first three months of 1922. It was equivalent to about 6 cents a dozen or an additional ad valorem of 4.27 per cent on the hosiery subject to the compensatory duty during the first quarter of 1922.

The act of 1922 abolished value classifications and levied a flat rate of 50 per cent ad valorem on all cotton hosiery other than cut hosiery, which was made dutiable at 30 per cent ad valorem.

COMPETITIVE CONDITIONS.

Conditions throughout the world have been so abnormal since the passage of the tariff act of 1913 that it is impossible to estimate what would have been the effect of the lower rates provided by that act if German trade had not been interrupted by the war. It is evident that the domestic hosiery industry as a whole has flourished both before and since 1914. The decrease in the production of cotton hosiery was in nowise the result of foreign competition, but of a change in the character of hosiery called for by the trade. Domestic competition is keen. There are many large mills with carefully built-up, well-financed organizations, but frequently the most telling competition is from small mills, having inadequate cost systems, that make their terms according to the market of the day. From 1916 to 1920 prices in general maintained such a high level, and manufacturing profits either were or appeared to be so alluring, that many men with some experience and a little capital undertook the manufacture of hosiery. Many of the concerns so formed have been unable to withstand the economic pressure of shrunken markets and the general business depression since 1920.

Wages in the knit-goods industry in this country show a tendency to decrease. The following tabulation gives the average weekly earnings in the cotton and woolen hosiery and knit-goods industries of New York State as compiled by the department of labor of that State and issued in their monthly industrial bulletin:

1922, June	$16.80
1921, June	18.50
1920, June	21.12
1918, April	14.38
1917, August	11.91
1916, June	10.23
1915, August	9.45
1914, August	8.68

There has been a decrease of about 38 per cent since 1921, though wages are still almost 100 per cent above the 1914 average. It must be borne in mind, however, that the more extensive production of fine goods calls for a greater proportion of skilled labor; a 100 per cent average wage increase therefore does not necessarily represent a 100 per cent increase in labor costs.

Germany in past years has been the only country sending any quantity of cotton hosiery into the United States, and even German imports, when compared with the output of the American industry as a whole, could hardly be considered competitive. The German product, full-fashioned hosiery, is superior to the American seamless, and will compete with it if sold at the same or a slightly higher price. A low labor cost has always been the determining factor in Germany's dominance of hosiery exports. No up-to-date figures for German wages are available: undoubtedly they are lower than the American, but constantly changing conditions make comparisons valueless. The German industry (1922), while apparently

making great strides toward the recovery of its normal efficiency, is beset by many difficulties. The position of labor since the revolution is stronger than during the old régime. The power of the unions has forced unemployment legislation, the 8-hour day and other industrial regulations which make labor costs in relation to wages greater than before the war. Wages are still very low, in some cases lower than in 1914 when the depreciated value of the mark is taken into consideration. The unions have obtained frequent raises in wages, but these have not counteracted the effect of the falling exchange. Apparently there has been no scarcity of labor such as might have been expected after the war.[6] Immediately after the war American manufacturers had some advantage in the facility of obtaining raw material, but this is hardly true at the present time because the German hosiery mills have a fairly active export trade and their capital is quickly released for reinvestment in raw materials. Fine cotton yarn which they get from England bears an import duty but this duty is merely nominal, amounting on the finest yarns at present rates of exchange (August 11, 1922) to a little over 1 cent per pound in comparison with an ad valorem duty of 27½ per cent on the finest yarns imported into the United States.[7] For this reason English yarns are cheaper in Germany than in the United States. The Germans import their fine yarns and probably will continue to do so in even larger quantities, because two of the largest spinning mills have been bought by linen interests and will no longer be used to spin cotton yarn. American manufacturers are becoming rather more than less independent in this regard, as finer yarns are being spun in the United States.

In Germany the hosiery industry, as is practically every other, is handicapped by the coal shortage. This has been occasioned by deliveries to the Entente, loss of mines in territorial readjustments, inadequate transportation facilities, and lack of capital for new undertakings.[8] The coal situation in the United States may occasion some shortage and increase in fuel costs, but the condition seems more temporary than in Germany.

Apparently, German industry is not on a very sound basis. The fluctuation of the mark tends to increase the export trade by introducing an element of speculation, but this can not result in permanent advantage to the German manufacturer. Stabilization of the currency would cause a narrower margin between prices in Germany and elsewhere. German manufacturers will probably continue to have some advantage in goods requiring a large proportion of labor, such as the infants' socks made with tops in Jacquard design.

---

[6] Metzner, Dr. Max, secretary cotton industry section of Federal Council of German Industry, Textile World Journal, Nov. 19, 1921.

[7] Kelly's Customs Tariffs of the World, 1923. The duties were raised by a 40 per cent April, 1922, or 6,000 paper marks, considered the equivalent of 100 gold marks. With the mark at par, duty under the unrevised tariff would have been about 1 cents per pound.

Cotton hosiery, fashioned or seamless—Rates of duty.

Act of—	Par.	Tariff classification or description.	Rate of duty.
1883	323	On stockings, hose, half-hose * * * fashioned, narrowed, or shaped wholly or in part by knitting machines or frames, or knit by hand, and composed wholly of cotton.	40 per centum ad valorem.
1890	353	Stockings, hose, and half-hose, selvedged, fashioned, narrowed, or shaped wholly or in part by knitting machines or frames, or knit by hand, including such as are commercially known as seamless stockings, hose or half-hose, all of the above composed of cotton or other vegetable fiber, finished or unfinished, valued at—	
		Not more than 60 cents per dozen pairs	20 cents per dozen pairs plus 20 per cent.
		More than 60 cents and not more than $2 per dozen pairs	50 cents per dozen pairs plus 30 per cent.
		More than $2 and not more than $4 per dozen pairs	75 cents per dozen pairs plus 40 per cent.
		More than $4 per dozen pairs	$1 per dozen pairs plus 40 per cent.
1894	262	Stockings, hose and half-hose, selvedged, fashioned, narrowed, or shaped wholly or in part by knitting machines or frames, or knit by hand, including such as are commercially known as seamless or clocked stockings, hose, or half hose * * * all of the above composed of cotton or other vegetable fiber, finished or unfinished.	50 per centum ad valorem.
1897	318	Stockings, hose and half-hose, selvedged, fashioned, narrowed, or shaped wholly or in part by knitting machines or frames, or knit by hand, including such as are commercially known as seamless hose, and half-hose, and clocked stockings, hose or half-hose, all of the above composed of cotton or other vegetable fiber, finished or unfinished, valued at—	
		Not more than $1 per dozen pairs	50 cents per dozen pairs plus 15 per cent.
		More than $1 and not more than $1.50 per dozen pairs	60 cents per dozen pairs plus 15 per cent.
		More than $1.50 and not more than $2 per dozen pairs	70 cents per dozen pairs plus 15 per cent.
		More than $2 and not more than $3 per dozen pairs	$1.20 per dozen pairs plus 15 per cent.
		More than $3 and not more than $5 per dozen pairs	$2 per dozen pairs plus 15 per cent.
		More than $5 per dozen pairs	55 per centum ad valorem.

TABLE 14.—*Cotton hosiery, fashioned or seamless—Rates of duty*—Continued.

Act of—	Par.	Tariff classification or description.	Rate of duty.
1909	328	Stockings, hose and half-hose, selvedged, fashioned, narrowed, or shaped wholly or in part by knitting machines or frames, or knit by hand, including such as are commercially known as seamless stockings, hose and half-hose, and clocked stockings, hose and half-hose all of the above composed of cotton or other vegetable fiber, finished or unfinished, valued at—	
		Not more than $1 per dozen pairs	70 cents per dozen pairs plus 15 per cent.
		More than $1 and not more than $1.50 per dozen pairs	85 cents per dozen pairs plus 15 per cent.
		More than $1.50 and not more than $2 per dozen pairs	90 cents per dozen pairs plus 15 per cent.
		More than $2 and not more than $3 per dozen pairs	$1.20 per dozen pairs plus 15 per cent.
		More than $3 and not more than $5 per dozen pairs	$2 per dozen pairs plus 15 per cent.
		More than $5 per dozen pairs	55 per centum ad valorem.
1913	260	Stockings, hose and half-hose, selvedged, fashioned, narrowed, or shaped wholly or in part by knitting machines or frames, or knit by hand, including such as are commercially known as seamless stockings, hose and half-hose, and clocked stockings, hose and half-hose, all of the above composed of cotton or other vegetable fiber, finished or unfinished; if valued at—	
		Not more than 70 cents per dozen pairs	30 per centum ad valorem.
		More than 70 cents, and not more than $1.20 per dozen pairs	40 per centum ad valorem.
		More than $1.20 per dozen pairs	50 per centum ad valorem.
1921	16	Cotton having a staple of one and three-eighths inches or more in length.	7 cents per pound.
	17	Manufactures of which cotton of the kind provided for in paragraph 16 is the component material of chief value.	7 cents per pound, in addition to the rates of duty imposed thereon by existing law.
1922	916	Hose and half-hose, selvedged, fashioned, seamless, or mock-seamed, finished or unfinished, composed of cotton or other vegetable fiber, made wholly or in part on knitting machines, or knit by hand.	50 per centum ad valorem.

COURT AND TREASURY DECISIONS.

Elastic stocking for varicose veins were declared not to be hosiery for tariff purposes under the act of 1890. They were classified as in chief value of silk or of cotton. (G. A. 666, T. D. 11383, of 1891.)

Men's cotton hose or half hose, made either with woven or knitted material, so fashioned by cutting and seam stitching as to resemble full-fashioned hose except the top portion, which is made of knit material joined together by a blind-seam stitch to the body of the hose, was held dutiable under paragraph 317 and not under paragraph 318 of the act of 1897. (G. A. 4657, T. D. 22007, of 1900.)

Cotton hosiery ornamented with clocking was held to be provided for as clocked stockings in paragraph 318 of the act of 1897 and not to be subject to the portion of the proviso in paragraph 339 for embroidered articles (G. A. 4715, T. D. 22268, of 1900; G. A. 6365, T. D. 27344, of 1906), but cotton hosiery embroidered with silk was held to come within the embroidery proviso in paragraph 339 of that act and subject to duty thereunder whenever such duty exceeded the compound rates imposed in paragraph 318. (Carter *v.* United States, 143 Fed., 256, of 1906; writ of certiorari denied, 202 U. S., 617, of 1906.)

The reenactment of the proviso to paragraph 339 of the act of 1897 in paragraph 349 of the act of 1909 with a limitation to articles or fabrics composed of flax or other vegetable fiber, while the old provision was not limited as to material, was construed not to warrant a different construction than that placed upon the proviso under the act of 1897 except in instances where the limitation as to material would apply. Cotton hosiery, embroidered, was held to come within paragraph 349 rather than within paragraph 328 of the act of 1909. (Abstract 29311, T. D. 32714, of 1912.)

The proviso was not reenacted in the act of 1913, but the phrase "by whatever name known" was inserted in the embroidery clause, and this was declared to withdraw from the other paragraphs of that act all embroidered articles just as surely as did the proviso in the acts of 1897 and 1909. (G. A. 7644, T. D. 34930, of 1914.)

Chain-stitched hosiery classified as embroidered wearing apparel under paragraph 339 of the act of 1897 was held dutiable as cotton hosiery under paragraph 318. (Abstract 22461, T. D. 30234, of 1909, following G. A. 4225, T. D. 19807, classifying cotton stockings, hose, or half hose, knitted in stripes of different colors running crosswise or transversely, subsequently chain-stitched longitudinally with single strands of silk or cotton thread on a sewing machine to come within paragraph 318 and not 339.)

The provisions in paragraphs 318 and 319 of the act of 1897 relating to stockings, hose, half hose, etc., were declared more specific than paragraph 347 for manufactures of ramie, vegetable fiber, etc., and held to include any hose of ramie. (G. A. 6304, T. D. 27177, of 1906.)

Infant's socks looped or knitted at the junction of the heel and sole were held dutiable under paragraph 328 of the act of 1909. (T. D. 31753, of 1911.) Under the act of 1909 in determining the component material of chief value in hosiery composed of silk and cotton the value of the cotton and silk in the gray condition just before the operation of making the article begins was taken. (Abstract 28633, T. D. 32560, of 1912.)

Children's cotton hose and half hose, made from fabrics knitted on two different types of machines and shaped by cutting and seam-stitching, were held to come within the provision "stockings, hose, and half hose, made on knitting machines or frames." (G. A. 7414, T. D. 33085, of 1913.)

COTTON GLOVES.

SUMMARY.

DESCRIPTION AND CLASSIFICATION.

Cotton gloves may be divided into four classes: (1) Canvas or flannel work gloves; (2) gloves made from tubular (circular) knit fabric; (3) lisle gloves; (4) suèded cotton gloves made of knit "Atlas cloth." The last class overshadows all the others in interest, so far as concerns its relation to the tariff. The manufacture of these

gloves is one of the industries that has grown up in this country as a result of the war, and the persons who are interested in it feel doubtful about their ability to compete with foreign manufacturers after normal trade conditions are restored. The tariff has never affected the manufacture of work gloves to any extent, and the other classes of gloves mentioned are produced and used in the United States in relatively unimportant quantities.

DOMESTIC PRODUCTION.

Quantity.—Several million dollars worth of work gloves are produced annually in this country, although the total output is difficult to estimate. These gloves are very often made of combinations of cloth and leather, the component material of chief value being as often leather as it is cloth. The value of the annual production of work gloves made entirely of cotton cloth may be conservatively estimated, however, at $3,000,000 to $4,000,000. The value of the annual output of gloves made of tubular knit fabric is about $400,000. The value of the output of lisle gloves is small, probably not reaching as large a total as the value of the gloves of tubular knit fabric. Probably about 1,300,000 dozen pairs of suèded cotton gloves, valued (price at factory) at $8,450,000, or $6.50 per dozen pairs, were manufactured in 1918.

Methods and processes.—The manner in which the Atlas cloth is made prevents it from raveling and makes it firm and strong. It will not stretch the longitudinal way of the weave after being shrunk, and this permits the production of a glove which will not stretch lengthwise, but will have elasticity across the palm so that it will shape itself to the hand and fit well. The Atlas process is often spoken of as a "weave," but the process is really knitting. The knit fabric, however, is such a close texture that it resembles a woven fabric.

Many technical difficulties have been encountered by the American manufacturers; in fact, they are just emerging from the experimental period. The suèding and the combining, or "duplexing," are both secret processes, and the method of each manufacturer differs slightly from the others. The suèding process has reached a more advanced state in this country than the duplexing. Very few duplex gloves were placed on the market by American manufacturers before the fall of 1918. The scarcity of gloves, and also of Atlas cloth made it more advantageous for the American manufacturers to make gloves of single thickness. There is, besides, a much larger market for the single-fold gloves, partly because of the difference in price and partly because they can be worn at all seasons.

In many respects the domestic product is just as good as the German—possibly better—but it seems difficult to duplicate the velvety finish of the imported gloves, which are an almost perfect imitation of chamois.

Materials and equipment.—Before the war the yarn used in making Atlas cloth came principally from Manchester, England. It was usually spun from Egyptian cotton. Stocks of yarn of this sort in this country were quickly reduced after the war began, and yarn of domestic make has been used with satisfactory results.

The warp knitting machines used to produce this glove fabric were made in Nottingham and Leicester, England, and in Chemnitz, Germany, before the war. Most of the machines used in this country have been imported; some of them were made by the Acme Pattern Co. of Buffalo, N. Y., and some of the manufacturers of the Atlas cloth have built machines for their own use.

Organization and capitalization.—Cotton gloves of all the varieties mentioned are made chiefly by small concerns. The average firm of glove makers works with a capital of about $50,000, although there are a few concerns with a capitalization of more than $500,000. The suèded cotton gloves are made in several instances by companies previously engaged in manufacturing leather gloves, silk gloves, veilings, or lingerie. Some of these concerns are larger than the typical glove manufacturing company, but most of them are small.

Localities of production.—Work gloves are made by many small companies scattered through the Middle West (chiefly in Ohio, Indiana, Illinois, and Wisconsin) and on the Pacific coast (principally in California). "Circular" cotton gloves have been made by a few small companies located in New York City and vicinity. Lisle gloves and suèded cotton gloves are made in New York City and vicinity and in Fulton County, N. Y., the great center of the leather-glove industry of this country.

Relation of domestic production to domestic consumption.—Practically all of the work gloves used in this country are made here. Prior to 1914, all of the suèded cotton gloves were imported, but for several years the German gloves could not be obtained and domestic manufacturers began to supply the market. The reentry of Germany in foreign trade has curtailed American production. Probably 75 per cent of the circular cotton gloves used here just before 1914 were made in this country, while now the domestic producers control the entire market. All of the lisle gloves were imported before the war. Domestic concerns began the manufacture of these also during the war, though probably about 50 per cent were supplied by Japan.

FOREIGN PRODUCTION.

Countries of largest production.—German manufacturers of cotton suèded gloves had practically a world monopoly prior to 1914. This industry was centered in and around Chemnitz, Saxony. Some gloves of this description were made in England, but very few compared with the number produced in Germany. Although the German factories continued to operate for some time after the war began, for a few years they were entirely shut off from other foreign markets. This was one of the first German industries to respond to post-war activities. Japan has made cotton gloves since 1914. The output of the Japanese factories has been chiefly lisle gloves. Some suèded gloves are made but the quality is altogether inferior to the German product.

IMPORTS.

Before the European war, 90 per cent of the cotton gloves imported into the United States came from Germany. Although German gloves were practically excluded for a few years they have

now regained their former position. Imports from Japan, which were comparatively large in 1919 and 1920, were insignificant in 1921 and the first quarter of 1922.

TARIFF HISTORY.

Under the tariff laws of 1894 and 1897 the import duty on cotton gloves was 35 per cent ad valorem. Cotton gloves were not specially enumerated under those acts but were included in "clothing, ready made, and articles of wearing apparel of every description. * * * composed of cotton or other vegetable fiber." From 1894 to 1897 the rate of duty on such articles was 40 per cent ad valorem.

In 1909 a clause was added to the hosiery paragraph (Schedule I, par. 328) providing for a duty of 50 cents per dozen pairs plus 40 per cent ad valorem on men's and boys' cotton gloves, knit or woven, valued at not more than $6 per dozen pairs, and 50 per cent ad valorem on men's and boys' cotton gloves valued at more than $6 per dozen pairs. All other cotton gloves remained dutiable, by the law of 1909, under the wearing-apparel paragraph at 50 per cent ad valorem.

In 1913 "gloves, by whatever process made, composed wholly or in chief value of cotton," were made dutiable at 35 per cent ad valorem (Schedule I, par. 260).

The emergency tariff act of May 27, 1921, levied a duty of 7 cents a pound on all articles made of cotton having a staple of 1⅛ inches or over. This affected most of the imports of cotton gloves.

The act of 1922, paragraph 915, divides cotton gloves into three classes: (1) Chamoisette gloves, made of warp-knit fabric, dutiable at specific rates, with a minimum of 40 per cent and a maximum of 75 per cent ad valorem; (2) other knit gloves, dutiable at 50 per cent ad valorem; and (3) gloves made of cotton cloth, dutiable at 25 per cent ad valorem.

GENERAL INFORMATION.

TARIFF ACT OF OCTOBER 3, 1913.

PAR. 260. * * * Gloves by whatever process made, composed wholly in or chief value of cotton, 35 per centum ad valorem.

DESCRIPTION.

Work gloves.—The United States is the only country in the world in which the manufacture of work gloves is of any importance. The gloves are made in more than a hundred styles and are used in a large number of industries—from candy making to shipbuilding. These gloves are very often made of canvas, with a palm reenforced by leather; sometimes, as in the case of gloves used for husking corn, they are reenforced with metal as well as with leather.

Gloves made of "circular" knit fabric. These gloves are so called because they are made of cloth manufactured on a machine similar to that on which knit underwear is made. The web comes from the machine in tubular form, and the product is cheap and of light weight. The gloves are cut from the piece and are sewed together as are leather gloves. They are not "knit goods" in the sense of

being turned out in final form by a special knitting machine. With the exception of work gloves, practically the only kind of cotton gloves made in this country before 1914 were the cheap cotton gloves of this circular knit fabric. These gloves are worn by policemen, soldiers, and sailors, and by lodges and fraternal orders on dress occasions and parades.

Lisle gloves.—This term is an inclusive one for gloves made of lisle (gassed) yarns, and it embraces many varieties of women's dress gloves. The gloves coming within this classification are made of various grades and qualities of knit cotton fabrics and are of much better quality than the gloves made of circular knit fabric. They differ from the suèded cotton gloves in the knitting and finish of the cloth. Before the day of suèded gloves they were in great demand for summer wear.

Suèded cotton gloves.—These gloves are commonly referred to as "Chamoisette" gloves, but the correct trade name is "suèded cotton" gloves. "Chamoisette" is used because the Julius Kayser & Co. advertised the suèded cotton glove, which they import from Germany under that name. Other companies apply different names to the same kind of glove. "Suedetex" is the name given by the Suedetex Glove Co.; "Fabrichant," by H. S. Hall & Co.; "Filosette," by Fownes Bros. & Co.; "Atlasette," "Suède finish," etc., are applied to the product by others. The gloves are washable, and are light and comfortable for summer wear. The duplex gloves, made of two thicknesses of the cloth, cemented together, are suitable for winter wear. The popularity of these gloves is increasing on account of their intrinsic merit, and because they are a good substitute for leather gloves, which have advanced greatly in price.

Gloves made of a single-fold material sometimes called "simplex" in contradistinction to the duplex gloves are in much greater demand than the latter because they can be worn at all seasons of the year and because they are much more reasonable in price. The popularity of these gloves is increasing on account of their intrinsic merit and because they are a good substitute for leather gloves which have become so expensive. The quality of the suèded glove is determined by the yarn used, the closeness of the knitting, and the finish. Some comparison as to quality can be obtained by examining the wrong side of a single-fold glove which will show minute horizontal ridges or rows of loops. Generally speaking, the greater the number of ridges to the inch the finer the quality.

RAW MATERIALS.

England is the principal producer of fine cotton yarns. As glove fabric requires yarn of comparatively high count, manufacturers both in Germany and America usually obtain Lancashire yarns. The German manufacturer is required to pay a duty on the yarn which he imports, but this is extremely small compared to the American duty on fine yarns. (See Cotton hosiery, page 22.) The yarns used are mainly 78/1 and 80/1 gray combed Egyptian. American yarns spun from long-staple uplands and Pima cotton have given satisfactory results.

PROCESSES OF MANUFACTURE.

Knitting machines of the Atlas type are used for making the fabric out of which the suèded cotton gloves are manufactured. These are warp knitting machines known as "flat" knitting machines, as distinguished from circular knitting machines on which circular fabric is made. The processes of knitting are entirely different and result in very dissimilar fabric. On a warp knitting machine hundreds of ends are supplied to the machine at one time from a series of bobbins or from a huge beam as are the warp ends in weaving. These threads are knitted simultaneously by an equal number of needles, a sidewise motion interlocking the loops horizontally. "Atlas cloth" is the trade name for the suèded cotton glove fabric; a special pattern wheel is used on the machine when this cloth is made.

The circular machine is a weft knitting machine utilizing only one or a few yarn ends which are knit horizontally into the fabric. The important advantages of the warp-end fabric are that it will not ravel as does Jersey cloth or as any fabric made on a circular knitting machine, and that it will not stretch the longitudinal way of the web after having been shrunk. It will stretch somewhat across the web. This enables manufacturers to produce a glove which does not stretch lengthwise, but which has elasticity across the palm so that it shapes itself to the hand and fits well. Warp knitting machines of this type, sometimes distinguished by the term "fast warp," were built in Chemnitz before the war and also in England at Nottingham and Leicester. The Acme Pattern Co., of Buffalo, N. Y., now builds them, and some of the makers of glove fabrics have built a few machines for their own use.

The next process after the fabric is knit is shrinking. The knit web is wet and stretched on frames in a very hot room until it is shrunk the required amount. The shrinkage varies considerably according to the yarn used, the closeness of the knitting, and the type of glove desired. The time consumed in this process is said to be anywhere from 3 to 30 days. Gloves are frequently designated as unshrunk, one-half shrunk, fully shrunk, or by intermediate terms. American manufacturers maintain that even the gloves known commercially as unshrunk probably have been subjected to the process as even the closest knitting will not produce a fabric sufficiently firm to give the desired suède effect.

After the fabric is shrunk it is ready for the suèding or napping. This has been one of the most difficult parts of the whole glove-making processes to master, the only other part which has given much trouble being the "combining" or duplexing—i. e., cementing two thicknesses of the fabric together—for use in the duplex gloves which are worn in the autumn and the winter. Suèding is a secret process, and each manufacturer has worked out a method of his own. Experimentation in this line cost the American manufacturers a considerable amount before the production of gloves had attained a commercial scale. The suèding machine consists of a series of rollers, covered with emery paper or sandpaper, over which the fabric passes. The wire rolls, which are used in raising the

nap on flannel, are too harsh for the Atlas cloth. Rolls covered with brushes or with cloth are used to give a smooth finish to the cloth. There are other operations which are not divulged by the possessors of the secret. In some factories cloth undergoes as many as 18 processes in being finished.

The process of cementing together two thicknesses of the knit fabric is called "duplexing." Manufacturers have had much difficulty in getting this properly done. Either the cement would show through the fabric after the gloves were washed, making black spots, or it would not be strong enough and the layers would separate. The preparation used could hardly be called cement, because when two layers of fabric are separated, after having been properly combined, there is found to be nothing between them, in the nature of a solid substance, such as would appear if ordinary glue or paste were used. Sometimes, when the work is not well done, the cement dries, the two thicknesses separate, and the dry particles of cement come out like grains of sand; this does not happen when the work has been properly done.

Only a small proportion of the knit fabric goes through the process of duplexing. More gloves are made of the single-thickness fabric than of the double thickness, and this was especially true of the situation during 1917, because it was hard to get enough fabric to satisfy all demands. The operations through which the knit fabric passes on its way to the finished glove are as follows:

(1) The fabric is knitted and cut into rectangular pieces of the right size for the gloves which are to be made; (2) the gloves are cut; (3) the size of the glove is stamped on the inside of the wrist; (4) the "points," or decorative lines, usually three in number, are sewed on the back of the glove; (5) the ends of silk thread are pulled through to the inside of the glove; (6) second silking (it is customary to do the silking in two operations, as it requires a combination of threads to make a point which looks well); (7) the remaining ends of silk threads are pulled through to the inside of the glove and all the ends are fastened by being tied; (8) thumb closing (that is, the top of the thumb is sewed up); thumb inserting (the thumb, which is cut separately from the rest of the glove, is inserted); (10) fourchette inserting (the fourchettes are the narrow strips which are sewed in making the sides of the fingers); (11) putting in the stays, which are small pieces of cloth designed to reinforce the glove at weak points; (12) closing (this process consists of sewing up the fingers); (13) hemming the edge of the wrist; (14) examining the glove for defects up to this point; (15) "laying off" (this consists in smoothing and pressing the glove on a heated brass form); (16) making buttonholes; (17) putting on buttons; (18) trimming loose ends of threads; (19) examining and repairing; (20) banding; (21) boxing; (22) shipping.

The fast-warp knitting machines are very large, the standard being about 180 inches wide. The mechanism is intricate and the operation heavy. Highly skilled labor is required for their manipulation. The operatives are always men, as is also the case in the other processes of making the fabric, such as the shrinking and dyeing. In the actual manufacture of the gloves, however, about 90 per cent of the workers are girls and women. The sanitary and other conditions prevailing in the knitting mills are about the same as conditions in the textile

industry in general. The glove-making business seems to be clean and healthful.

The workers are paid by the piece, almost invariably. The trend of wages in the suèded cotton-glove industry, which did not exist prior to the war, is similar to that of the entire knit-goods industry in New York State as given on page 21, because practically all of the glove-making concerns are located in that State. It so happens that a large part of the industry is in localities where there is great competition for similar labor in periods of prosperity. Hence the average wage in this industry is probably somewhat above the average wage in the knit-goods industry.

Most of the work of manufacturing suèded cotton gloves is done in factories. The only place where there is any considerable amount of putting out work is Gloversville, N. Y. In that city a large number of women take work to do in the home. Many of them have motors installed in the homes, and the sewing is done on power-driven sewing machines. Women who do this work are often former employees of the glove factories.

HISTORY OF THE INDUSTRY.

Prior to the European war the suèded cotton glove was made almost exclusively by manufacturers in Chemnitz and surrounding villages of Saxony. The industry originated in England, but became established in Chemnitz about 1906, and subsequently was entirely discontinued in England.

In 1913 England received over 2,500,000 dozen and the United States over 1,500,000 dozen pairs of cotton gloves of German manufacture.

The German product had reached a very high degree of perfection. The gloves were an excellent imitation of chamois or undressed kid, and were made in all the familiar glove shades—mocha, yellow or cream, brown, and black, as well as white. There was some criticism, however, of the style and fit of the German gloves.

Soon after the European war began, certain American manufacturers undertook the business of making suèded cotton gloves in anticipation of the cessation of imports from Germany. The firms which interested themselves in this business had been manufacturing leather or silk gloves before the war, or, in a few cases, were concerns which had been making veilings, lingerie, and women's apparel of other kinds.

The business of manufacturing the suèded cotton glove grew very slowly at first on account of the technical difficulties involved. A great deal of experimentation was necessary before the American manufacturers could weave and finish as good an Atlas cloth as that which had been used by the German manufacturers. The importations of German gloves continued for some time after the war began, but in 1916 there was a marked diminution in the imports, and the domestic manufacture was correspondingly stimulated. Another fact which operated to encourage the manufacture of these gloves was the great increase in the price of leather gloves. This subject is discussed under the heading "Rival commodities, page 43."

made glove. The retailers were willing to push the sales of the poorer gloves because of the slight advantage in price which they obtained. Both German and American gloves sold, however, for the same retail price—10 cents a pair.

Notwithstanding the fact that the American manufacturers were able to continue in the cotton-glove business after 1913, they assert that the margin of profit was very small and that they intended, if the war had not intervened, to invest their capital in some other more productive line. One manufacturer stated that he could have made $50 a week if he had not been obliged to pay a factory superintendent. It appears that the business was just paying costs, including the wages of superintendence.

RIVAL COMMODITIES.

The increasing price of leather gloves after the outbreak of the war had the effect of causing women to turn to the suèded cotton gloves as a substitute for the leather gloves. The percentage of increase in price of the suèded cotton gloves was as great as the percentage of the increase in the price of leather gloves. The price of the suèded cotton gloves to the importers ranged, before the war, from $2.50 to $5 per dozen pairs, and the gloves sold for 50 cents to $1 per pair at retail. In 1918, the price for the domestic product ranged from $1 to $2 per pair at retail. Leather gloves, on the other hand, increased from their former price of $1 to $2 a pair to an average of $2 to $4 a pair retail. It is evident that an increase in the price of an article from $2 to $4 means that there will be substituted for such an article some product which has increased from a former average of 50 cents to an average of $1. This was the situation in regard to the leather gloves and the suèded cotton gloves, and this fact greatly stimulated the domestic manufacture of the suèded cotton gloves.

The various branches of the glove business are all closely related and the growth of a new industry, such as the making of suèded cotton gloves, naturally affects the makers of silk and leather gloves. Many manufacturers who formerly devoted all their attention to making leather gloves bought the suèded cotton cloth from which to make gloves.

METHODS OF MARKETING.

Some of the leading manufacturers of the suèded cotton gloves sell through jobbers, but the majority of them have a copyrighted name or trade-mark for their product and sell direct to the retailers. Those who are engaged in marketing the gloves are, for the most part, manufacturers of and dealers in women's wear of various kinds. A number of them also have been interested for some time in the leather-glove or silk-glove business. Few companies have been organized expressly for the purpose of placing these gloves on the market. They were taken up as a promising side line by those already engaged in a similar line of business but have become in some instances of more importance than any other class of goods sold by the firms handling them.

PRODUCTION IN THE UNITED STATES.

The following is an estimate, based upon statements of the manufacturers, of the value of the domestic production of men's and boys' cotton gloves, of the kind commonly worn by policemen, manufactured after the passage of the act of 1909, which levied a duty of 50 cents per dozen pairs and 40 per cent ad valorem on this class of gloves. For purposes of comparison the imports of these gloves are also given.

TABLE 1.—*Men's and boys' cotton gloves.*

Year.	Domestic production (estimated).		Imports for consumption,[1] value.
	Quantity.	Value.	
	Dozen pairs.		
1910		$250,000	$122,760.00
1911		250,000	165,840.00
1912		300,000	88,362.78
1913		300,000	88,699.00
1914		150,000	22,961.72
1915		75,000	[2]
1916		150,000	[2]
1917		300,000	[2]
1918		400,000	[2]
1919 [3]	133,968	494,000	[2]

[1] Imported as "men's and boys' cotton gloves, valued at less than $6 per dozen pairs."
[2] After the act of 1913 was passed all imports of cotton gloves were classified together in the Commerce and Navigation Reports. It is therefore impossible to tell the extent of imports of the cheap gloves after this date, but it is known that they declined after the European war began.
[3] From Federal Census; includes lisle gloves.

The output of work gloves is very difficult to estimate. These gloves are made of various combinations of cloth and leather. The total annual production must be worth several million dollars, as there are some large firms engaged in the business, but only a small proportion of this amount is represented by gloves made wholly of cotton.

The manufacture of suèded cotton gloves is an entirely new industry in this country. The following estimate of the quantity and value of the domestic production is based upon the statements of manufacturers:

TABLE 2.—*Domestic production of suèded cotton gloves.*

Year.	Number of dozen pairs.	Value.	Price at the factory, per dozen pairs.
1914	50,000	$200,000	$4.00
1915	200,000	1,000,000	5.00
1916	500,000	2,750,000	5.50
1917	1,000,000	6,000,000	6.00
1918	1,300,000	8,450,000	6.50
1919 [1]	289,179	.....	.....
1920	287,339	.....	.....

[1] Census figures give 163,086 dozen pairs, valued at $1,061,856.

The census figures for the production of suèded gloves are smaller than those of the Tariff Commission for the same year (1919), because census returns consider only the primary product of an industry

under a given classification. A large proportion of the cotton suèded gloves are made by manufacturers of leather gloves, and therefore would not be returned to the Census Bureau as products of the knit-goods industry. The Tariff Commission figures are in all probability too low, as they represent (1919 and 1920) the product of only the four concerns that answered the commission's inquiry.

FOREIGN PRODUCTION.

Germany.—Before the World War German manufacturers had obtained such perfection in the manufacture of suèded gloves that they practically shut out all other competition in the markets of the world. German export statistics are given by weight, and it is estimated from these weights and from imports into other countries that their foreign trade averaged between 7,000,000 and 8,000,000 dozen pairs annually. Great Britain was a market for over 2,500,000 and the United States for over 1,500,000. A representative of the manufacturers in Germany estimates that there are from 200 to 400 factories in Chemnitz and near-by villages. Most of these are comparatively small and have the dyeing and finishing of the cloth done outside.[1]

England.—Although England was originally the home of fabric glove manufacture, this trade was ruined by the success of German chemists and machine builders who were the first to impart to the suèded fabric a permanent black dye and a soft, skinlike appearance. The imports from Germany into England in 1913 amounted to 2,511,009 dozen pairs, valued at $3,523,000. This was a market worth striving for, and with the elimination of German competition English manufacturers, encountering much the same technical difficulties met by Americans, revived the cotton-glove industry. Glove fabric is made from fine yarn, the best of which is spun in England—even the Germans had imported theirs—so in one respect the English manufacturers had an advantage. Nottingham became the center of this trade and in 1918 produced four times the quantity of glove fabric that was produced in 1913. In 1920 it was said that the industry, still in its infancy, employed about 6,000 workers, but fear was expressed that its success would again be menaced by German competition.[2]

Although German trade in cotton gloves has shown renewed activity in the British market, imports have not reached the pre-war level as in the United States. However, British glove manufacturers, alarmed at the increase, have invoked the "safeguarding of industries act," which provides an import duty of 33⅓ per cent. This duty was imposed by a board of trade order on fabric gloves and glove fabric, if manufactured in Germany, to be effective from October 9, 1922, until August 19, 1924. There was vigorous opposition from the Lancashire spinners who supplied yarn to the German glove manufacturers and who fear that the Germans may retaliate by refusing to buy English yarn.

[1] In the files of the Tariff Commission there are several communications from representatives of associations of the German cotton-glove industry. These deal with the general conditions in the industry at the particular time when they were written, and as these conditions have changed rapidly they have not been quoted at length in this report.

[2] Dry Goods Economist, Oct. 23, 1920.

Imports into England from Japan by 1918 supplied about 50 per cent of the quantity which was formerly received from Germany, but so large a proportion of the home demand remained to be satisfied that English manufactuers did not build up a very extensive export trade.

Japan.—The cotton-glove industry of Japan probably shows a more marked expansion in quantity of output than that of any other country. Production amounted to 551,000 dozen pairs in 1913 and to 3,762,000 dozen pairs in 1918.[3]

The Japanese trade was transitory, for although they turned out enormous quantities at an exceedingly low cost, the quality was, for the most part, so inferior that other goods even at higher prices would be accepted. The following figures show the decline of Japanese export trade since the peak of 1918: 2,459,000 dozen pairs in 1918; 1,216,000 dozen pairs in 1919; and 403,000 dozen pairs in 1920.

France.—There were several manufacturers of fabric gloves in France prior to 1914, but as they bought their fabric in Germany they represented only the cutting-up end of the industry. When imports from that country were cut off the French began to build the fast-warp knitting machines and to make the required fabric.

The industry is still specialized to a great extent, and all the glove factories do not produce the knit fabric which they use. Paris, Lyon, and Grenoble are the principal centers; there are isolated factories in other parts of the country. The industry grew so rapidly with the removal of German competition that exports of cotton gloves from France increased from a value of a little more than $3,000 in 1913 to over $1,500,000 in 1917.

The quantity exported expressed in weight has been as follows:

Exports of cotton gloves from France.

Year.	Pounds.
1913	1,102
1917	248,238
1918	126,323
1919	174,163
1920	216,712
1921	82,673

Twelve pairs of gloves weigh from one-half pound to 2 pounds; about three-fourths pound per dozen pairs may be taken as an average.

Switzerland.—Much attention has been given to the various branches of the knit-goods industry in Switzerland in the last few years and that country is gradually gaining a place in the manufacture of fabric gloves. German machines, built at Limbach, were imported and by 1918 about 200,000 dozen pairs of gloves were being produced annually. The value of Swiss exports of cotton gloves amounted to about $600 in 1913, and to about $425,000 in 1919.[4]

IMPORTS.

Figures of domestic production may be compared with the imports of cotton gloves of all kinds. These imports were chiefly of suèded cotton gloves up to 1917; during 1917 and 1918 they were chiefly lisle gloves.

[3] Official Japanese statistics.

[4] L'Exportateur Suisse (periodical), March, 1920.

Prior to 1914 statistics of the Department of Commerce represented only men's and boys' cotton gloves, specially mentioned in the act of 1909. Comparing official import figures for these years with the estimated production of men's and boys' gloves (Table 1, p. 44) it will be seen that imports were 49 per cent of the domestic production in 1910 and about 28 per cent in 1913.

The imports of women's and children's cotton gloves, of which there was practically no corresponding domestic production, were included in "Cotton wearing apparel" (in the United States Commerce and Navigation Reports) prior to 1914, but their approximate amount may be determined from the following figures, from the Daily Trade and Consular Reports. These imports from Chemnitz represent about 90 per cent of the total imports of cotton gloves into the United States in the years mentioned.

The value of cotton gloves imported from Chemnitz, Saxony, to the United States in 1911 amounted to $1,211,000; in 1912, $1,741,000; and in 1913, $2,396,408.

The total imports of cotton gloves for each year, 1911–1913, would therefore about equal the sum of these figures and imports for consumption during corresponding years. Imports for 1913 were first in value; for 1915, second. From 1917 to 1920 imports were much smaller, the largest amounting to $590,684 in 1918.

Imports of cotton gloves were not given by countries until 1919. Japan supplied 97.8 per cent of the total during the year 1919, and 77.8 per cent in 1920. German gloves began to arrive again in 1919 and amounted, in 1920, to 16 per cent of the total from all countries.

Imports from Germany have practically reached the pre-war level. The total general imports of cotton gloves for the 12 months ended June, 1922, amounted to 1,595,125 dozen pairs, valued at $3,916,972. The imports for the first six months of 1922 were as follows:

TABLE 3.—*General imports of cotton gloves, six months, 1922.*

Month.	Dozen pairs.	Value.	Unit value.
January	104,304	$188,488	$1.81
February	110,631	236,777	2.14
March	173,462	434,729	2.51
April	144,473	369,651	2.56
May	147,040	366,910	2.49
June	165,122	484,009	2.93
Total	845,032	2,080,564	2.46

The monthly statistics of the Department of Commerce do not give the country of origin, but it is evident that practically all of these gloves come from Germany.

Imports of cotton gloves were not given by countries until the last half of 1918 (Table 7, p. 53). Japan supplied 90 per cent of the total quantity during the year 1919 and 41 per cent in 1920. German gloves began to arrive again in 1919, and in 1920 amounted to 57 per cent of the total from all countries; in 1921 to 97 per cent and the first quarter of 1922 to 98 per cent.

The gloves imported are said to be largely of the "unshrunk" variety, which could be bought in Germany for about $2.85 per dozen pairs in July, 1922. They represent some of the cheaper types made up without extra finishings in points and clasps, but are of an extremely good grade of suèded fabric.

PRICES.

Two pairs of suèded cotton gloves were submitted to the commission as samples. One pair, made in Chemnitz, Germany, bore the name of Alban Aurich. These gloves cost 7½ marks or $1.785 (less 5 per cent) per dozen pairs in Germany, in 1913. The landed cost in this country, after deducting the discount and paying the 35 per cent duty and 10 cents a dozen for expenses, was $2.40. Better grades of the suèded gloves were imported for $3.75 to $4.25 per dozen pairs, landed cost. The average price of the gloves to the retailer was about $4.50 per dozen pairs, and the usual price to the consumer was 50 cents a pair. The other sample pair submitted was an American product. Both cloth and gloves were made in this country. The particular yarn used in these gloves may not have been made from domestic cotton, but many of the gloves now being made in this country are made from American-grown cotton. Gloves similar to these were being sold in 1918 to jobbers for $6 to $7 per dozen pairs; to the retailers for $7 to $9 per dozen pairs, and to the consumer for $1 a pair, usually, although the cheaper grades were sometimes sold as low as 75 cents. The duplex gloves sold for $1.50 to $2 per pair.

A lisle glove was formerly sold for 35 cents at retail, but of late there has been nothing to take its place, except some cotton gloves of rather poor quality imported from Japan. Some of these cost as low as $2.35 per dozen pairs in Japan, and were sold for about 50 cents a pair at retail. There is a dearth of low-priced cotton gloves, as American manufacturers are devoting their attention to the better grades.

Gloves made of circular cotton fabric, made on a knitting machine similar to a stocking machine, have been sold for 10, 15, and 25 cents a pair at retail in the past. Gloves, like the sample submitted, sold for 10 cents a pair before 1909, and for 15 to 25 cents a pair from 1909 to 1913. After the rate of duty was reduced to 35 per cent, in 1913, the price fell to 10 cents a pair. Few American manufacturers are producing this kind of gloves, and most of those made are bought for the various branches of the service by the United States Government.

The imported suèded glove referred to as bought in Germany for $2.85 is sold to the retailer for about $4 and is retailed by him at about 50 cents a pair. An American glove, closely approaching this in style and quality, was sold at the mill in July, 1922, for about $4.85. A similar glove had been selling in the summer of 1921 for $6.50.

COMPETITIVE CONDITIONS.

Domestic competition.—Competition among the domestic producers never became very severe, because the demand was greater than their possible output up to the time the German gloves reentered

the market. Production in this country, however, was steadily increasing, and the time was not far distant when jobbers and retailers would have become more critical of the goods offered them. The increasing competition, which naturally would have followed the continuous expansion of the industry, would probably have tended to retard undue price advances. American manufacturers had arrived at a stage where they had overcome the initial disadvantages of experimentation and could devote their efforts largely to improving the quality of the gloves produced. The renewed activity of the German industry eliminated the incentive which they had for investing further capital, and in 1922 few American manufacturers were operating their plants.

Comparative costs of production.—Figures in regard to the comparative costs of production in the different countries are not of very great worth, particularly in a period of fluctuating wage levels. However, some figures were supplied the Tariff Commission by representatives of German manufacturers, and the commission procured from American manufacturers statements in detail as to their cost of production of similar articles. The results are given below, but owing to the conditions prevailing and to the lack of verification by official accountants, these are to be regarded as approximate rather than as precise comparisons.

TABLE 4.—*Comparison of estimated manufacturing costs of cotton suède-finished gloves, United States and Germany, 1921.*

	Cost per dozen pairs.		Per cent of total cost.

Total	1.62	100.00	3.17	100.00	2.71	100.00
Turnover and export taxes					.23	8.49

[1] Conversions made at the following rates: 1914, 1 mark=$0.2382; April, 1921, 1 mark=$0.046; January, 1922, 1 mark=$0.005204.

As production at the present time in the United States is not normal, costs have not been obtained to compare with the latest German costs supplied. From 2 to 2¼ square yards of fabric are required for one dozen pairs of short gloves. Estimated on the above costs of material and labor, the following comparison of American and German fabric costs has been calculated on a basis of 2 square yards to a dozen pairs of gloves, and secondly on a basis of 2¼ square yards to a dozen pairs:

TABLE 6.—*Comparison of American and German estimated costs of cotton suède-finished glove-fabric per square yard, 1921.*

	American.	German.	Difference.
Unshrunk cloth:			
At 2 square yards per dozen pairs	$0.82	$0.576	$0.244
At 2¼ square yards per dozen pairs	.73	.512	.218
Shrunk cloth:			
At 2 square yards per dozen pairs	1.09	.872	.218
At 2¼ square yards per dozen pairs	.97	.775	.195
Duplex cloth:			
At 2 square yards per dozen pairs	2.10	1.395	.705
At 2¼ square yards per dozen pairs	1.87	1.240	.630

Competition with Germany.—The respective merits of the German-made and American-made Atlas cloth and suèded cotton gloves are often discussed, but involve different standards. Large retailers in the country disagree radically. Some of them say that the American product has attained an excellence unsurpassed by any gloves which the Germans ever sent over. Others maintain that the American-made gloves are markedly inferior to the imported. There is substantial agreement, however, that American manufacturers are steadily improving the quality of their output, and very few persons deny that the domestic product is now at least almost as good as the Chemnitz gloves.

Some of the American manufacturers assert that there has always been criticism of the style and fit of the German gloves. They become "baggy" after a little wear, and furthermore the clasps and other small details of finish are not so good as those of the domestic product. In regard to the tendency of the German-made gloves to become baggy, the reason does not lie in the way the cloth is woven but in the manner in which it is shrunk, or perhaps better, the degree to which it shrunk. The more it is shrunk the less is its elasticity, and the German cloth is shrunk about to the maximum. The American-made gloves therefore seem to have much more elasticity. The principal point in which American gloves are inferior is the finish, or suèding. American manufacturers have not yet learned the secret of the beautiful velvety finish which makes the best German gloves almost a perfect imitation of chamois or mocha skin.

The German suèded cotton-glove industry seems to have recovered its normal productivity more rapidly even than other German textile industries, if we are to judge by exports. This is probably because the German suèded cotton glove was about the only one known in foreign markets prior to the war, and its present popularity is no doubt in large measure due to its former reputation. German gloves were always considered the standard of excellence, and when they could be obtained again at attractively low prices there was a rush of buyers to the glove-making district. This occasioned a tremendous boom, which does not necessarily signify that the industry will continue on any such scale of prosperity. The conditions that make the continued success of other industries in Germany a probability would also affect the glove industry. (See Hosiery, p. 15.) The good name of the German cotton suèded glove, combined with facilities of manufacture and secret processes in finishing, would give a German glove manufacturer some advantages not enjoyed by German industries in general.

Competition with Japan.—It has been difficult to obtain reliable figures as to the cost of production in Japan, especially labor cost. The fact that costs vary greatly within the country, explains some of the discrepancies in figures. It is stated, on good authority, that some of the work on gloves is done in "bush shacks," and that what costs one manufacturer 13 yen, costs another but 3 yen. It may safely be assumed that the actual labor cost of cotton gloves in Japan is low, because most of the work is done by women and girls. The Japanese are exceptionally quick to learn operations of that sort. Some of the American manufacturers, who have had Japanese operatives, report them to be as good as any workers ever employed in the industry.

Some of the importations from Japan in the spring of 1918 were brought in at $2.35 per dozen pairs (cost in Japan). The cheapest gloves imported from Germany before the war, with the exception of the gloves made from circular knit fabric, were valued at $2.25 per dozen pairs (landed cost); the Japanese have therefore been selling the gloves nearly as cheaply as the Germans did, although the quality of the goods was much below the German standard. Not many of the cheaper gloves have been made in the United States since 1914, and the dealers have had practically nothing to take the place of the lisle gloves that used to retail at 35 cents a pair until the gloves from Japan were brought in. The supply of cotton gloves of all kinds has been so small that it has been better for the domestic manufacturers to devote their whole attention to making the gloves of the better grade; consequently they have concentrated on the suèded gloves.

Status of the domestic manufacture.—The manufacture of suèded cotton gloves in this country is, in a sense, an "infant industry." Viewed from another angle, it is merely a new subsidiary or side line to an old industry, or rather several old industries, viz, the manufacture of silk gloves, of leather gloves, and of cotton cloth. Most of the machines for making the Atlas cloth and for sewing the gloves have been adapted to this new line of work from former utilization for the branches of manufacture mentioned. A special pattern wheel is put on a "tricot" knitting machine when it is used for making the Atlas cloth. The suèding process, however, requires the use of a highly specialized new machine. Ordinary napping machines, used in making cotton flannel, etc., will not do at all for the chamoisette. The wire rolls are too harsh, and a much finer roughing process must be employed. The duplexing process for cementing layers of the fabric together, which is done under hydraulic pressure, is another specialized operation. In glove making the same sewing machines will do for many kinds of fabric. Cotton gloves can be sewed on the machines on which light leather gloves are made or on those on which silk gloves are made.

It is an open question whether the American manufacturers can continue to make cotton gloves in competition with Germany after normal conditions are restored. American manufacturers are striving to secure high quality, excellent style, and good pattern in their gloves, and if they attain these desired ends they will be able to hold their own in the future, even against a lower priced imported glove. This is not their view of the situation, however; most of them have expressed the opinion that the present rate of duty is too low to enable them to meet foreign competition successfully.

The American industry in the summer of 1922 was practically at a standstill. It was more profitable to import than to manufacture suèded cotton gloves, and very few firms were making up any gloves in the face of the competition from the low-priced German goods. The stabilization of the German currency would remove much of the speculative element involved in buying in Germany and probably in general would tend to raise prices in that country. It can be seen from the monthly import statistics (p. 47) that the price of imported gloves, which were almost entirely German-made, gradually increased after the beginning of 1922.

STATISTICAL TABLES.

1897	314	* * * articles of wearing apparel of every description, * * * composed of cotton * * * or of which cotton * * * is the component material of chief value, * * *.	50 per centum ad valorem * * *.
1909	328	* * * Men's and boys' cotton gloves, knitted or woven:	
		Valued at not more than $6 per dozen pairs	50 cents per dozen pairs and 40 per cent ad valorem.
		Valued at more than $6 per dozen pairs	50 per cent ad valorem.
1913	256	* * * articles of wearing apparel of every description, composed of cotton * * * and india rubber * * *.	30 per cent ad valorem.
	260	* * * Gloves by whatever process made, composed wholly or in chief value of cotton.	35 per cent ad valorem.
	358	* * * wearing apparel * * * embroidered in any manner by hand or machinery, whether with a plain or fancy initial, monogram, or otherwise, * * *.	60 per cent ad valorem.
1921	16	Cotton having a staple of 1⅛ inches or more in length	7 cents per pound.
	17	Manufactures of which cotton of the kind provided for in paragraph 16 is the component material of chief value.	7 cents per pound, in addition to the rates of duty imposed thereon by existing law.
1922	914	Knit fabric, in the piece, composed wholly or in chief value of cotton or other vegetable fiber:	
		Made on a warp-knitting machine	55 per centum ad valorem.
		Made on other than a warp-knitting machine	35 per centum ad valorem.
		Gloves, composed wholly or in chief value of cotton or other vegetable fiber:	
	915	Made of fabric knit on a warp-knitting machine—	
		If single fold of such fabric—	
		When unshrunk and not suèded, and having less than 40 rows of loops, per inch in width on the face of the glove.	50 per centum ad valorem.
		When shrunk or suèded or having 40 or more rows of loops per inch in width on the face of the glove, and not over 11 inches in length.	$2.50 per dozen pairs.
		And for each additional inch in excess of 11 inches	10 cents per dozen pairs.
		If of two or more folds of fabric, any fold of which is made on a warp-knitting machine, and not over 11 inches in length.	$3 per dozen pairs.
		For each additional inch in excess of 11 inches	10 cents per dozen pairs.
		But in no case shall any of the foregoing duties be less than 40 nor more than 75 per centum ad valorem.	
		Made of fabric knit on other than a warp-knitting machine	50 per centum ad valorem.
		Made of woven fabric	25 per centum ad valorem.

COURT AND TREASURY DECISIONS.

In 1883 cotton gloves were omitted from the provision for goods made on frames. They were held to be dutiable either under that provision or as manufactures of cotton, which carried the same rate of duty. (T. D. 6248.)

But cotton gloves lined with wool, the wool constituting a substantial feature but not in chief value, were held dutiable under that act as wearing apparel composed in part of wool. (T. D. 6428.)

Under the acts of 1890 cotton gloves were held dutiable as wearing apparel and not as manufactures of cotton. (G. A. 546, T. D. 11187.) The same was true of so-called taffeta gloves of cotton, clocked with silk, cotton chief value. (G. A. 1540, T. D. 12989.) But taffeta gloves of cotton with silk threads of neat or thrown silk giving the gloves a silk face, the silk being the component of chief value, were classified as wearing apparel in chief value of silk. (G. A. 2144, T. D. 14145.)

Cotton gloves with silk points, consisting of plain rows of two or more strands of silk thread down the backs, were held dutiable as cotton wearing apparel embroidered. (G. A. 2584, T. D. 15007.)

Classification of cotton gloves as wearing apparel rather than as manufactures of cotton was continued under the act of 1894. (G. A. 2956, T. D. 15856.)

Gloves were held not to be garments, and men's cotton gloves having an elastic braid or band at the wristband for the purpose of holding them closely upon the wearer's wrists, were accordingly held under the act of 1897 not to be outside garments having india-rubber as a component material, because not a "garment." (G. A. 5023, T. D. 23356.)

Cotton gloves having three rows of stitching on the back, known as "kid point," were held not embroidered. (G. A. 4656, T. D. 22006.) But men's cotton gloves having four parallel lines of needlework near the top, giving the appearance of a scroll border, were declared both ornamental and useful and dutiable as embroidered wearing apparel. (G. A. 6461, T. D. 27663).

Gloves made of yarn, composed of cellulose filaments obtained from cotton waste by chemical treatment, were held dutiable by similitude as wearing apparel in chief value of cotton. (Thomass *v.* U. S., 1 Ct. Cust. Appls., 86.)

Cotton gloves knitted or woven needed not to be shaped by a weaving process nor knitted, fashioned, and shaped wholly by a machine to be classified under the provision in the act of 1909 for men's and boys' cotton gloves knitted or woven. (Spielmann *v.* U. S., 3 Ct. Cust. Appls., 368; Lehman Co. *v.* U. S., 5 Ct. Cust. Appls., 441.) But the provision was held not to include gloves lined with wool, which was declared to constitute a substantial and necessary part of the gloves and to enchance their value, add to their comfort and warmth, and aid in their sale. The provision for knitted articles in part of wool was held to govern classification. (U. S. *v.* Burne, 4 Ct. Cust. Appls., 298.)

Women's cotton gloves, not being specifically provided for, were held dutiable as cotton wearing apparel and not as manufactures of cotton under paragraph 324 of that act. (G. A. 7091, T. D. 30892.)

Women's gloves of cotton and silk, cotton chief value, were likewise classified. (Abstracts 33253, T. D. 33668 and 35852, T. D. 34548.)

An importation classified as men's and boys' gloves under paragraph 328 of the act of 1909 was found to be women's cashmere gloves dutiable under paragraph 324. (Abstract 35102, T. D. 34279.)

Gloves composed of cotton and rubber and used by electricians and linemen were held dutiable as wearing apparel under paragraph 256 of the act of 1913 as more specific than the provision for manufactures in chief value of rubber under paragraph 368. (Abstracts 37512 and 38390.)

Women's embroidered cotton gloves were held dutiable under paragraph 358 and not as cotton gloves. (Abstract 38251.)

Gloves classified as composed in chief value of silk at 50 per cent ad valorem under paragraph 317 of the act of 1913 were found to be in chief value of cotton and classified accordingly under paragraph 260. (Abstract 39964.)

COTTON KNIT WEARING APPAREL.

SUMMARY.

Knit cotton wearing apparel, exclusive of hosiery and gloves, consists largely of underwear. Although a considerable quantity of cotton is used in making knit outerwear—sweaters, toques, scarfs, etc.—it is usually in combination with wool or silk which, being a material of greater value, would govern in tariff classification.

The underwear industry is entirely independent of foreign resources, as the materials used, with the probable exception of relatively small amounts of fine-count yarns, are domestic, and the machinery, mostly of the circular type,[1] is built in this country. Moreover, the principal market for the product is the United States.

The American industry is well established, represented for the most part by large concerns, well equipped and efficiently conducted. Imports are insignificant compared with the total domestic output, being only about one-half of 1 per cent in 1914. However, as imports are concentrated in one class of goods—fine-grade underwear—there is more competition than appears from a comparison of total figures. These fine goods came principally from Germany and Switzerland; imports in recent years have been largely of coarser, cheaper articles from Japan.

GENERAL INFORMATION.

TARIFF ACT OF OCTOBER 3, 1913.

Par. 261. Shirts and drawers, pants, vests, union suits, combination suits, tights, sweaters, corset covers, and all underwear and wearing apparel of every description, not specially provided for in this section, made wholly or in part on knitting machines or frames, or knit by hand, finished or unfinished, not including such as are trimmed with lace, imitation lace, or crochet, or as are embroidered and not including stockings, hose and half hose, composed of cotton or other vegetable fiber, 30 per centum ad valorem.

DESCRIPTION.

Underwear.—The most important industry affected by paragraph 261 of the act of 1913 is the underwear industry. Knit underwear, like hosiery, may be classified according to the type of machine on which the knitting is done. Full-fashioned underwear, made on a flat-bed machine, is shaped in the knitting; cut underwear is cut from long tubes or webs of knitted fabric made on circular machines. Now that finishing machines have been brought to such perfection, the same superiority can not be claimed for full-fashioned underwear as for full-fashioned hosiery.[2] Quality is dependent upon the material used, the gauge of the knitting machine, and the workmanship throughout. As a matter of fact, full-fashioned underwear is usually of finer grade than "cut" underwear, but rather because of the yarn used and the labor expended than any intrinsic superiority in the process. The fit of a garment cut from tubular web fabric may be as perfect and the finish as excellent as of a full-fashioned article if the pattern used is satisfactory and the cutting done with accuracy and care and if the best seaming and overedging machines are used. One machine makes a perfectly flat elastic seam in which there is no overlapping of the material, the abutting edges being held firmly and neatly together by the interlocking of several parallel lines of stitching. As the production of circular underwear is much more rapid and cheaper than that of full-fashioned, it is more important in the United States. Knit underwear may be further classified according to the weight of the garment, the quality and finish of the material, and the stitch employed, but the above classifications represent the distinct lines of cleavage in the industry.

According to the nature of the fabric some of the more important classifications are flat, ribbed, fleece-lined, napped. "Flat" is a rather confusing term because it may apply to material knit on a flat, in contradistinction to a circular machine, but generally speaking the term "flat" when applied to finished underwear means a fabric in which the wales, or lines of knitted loops, all appear on the front or right side of the fabric, giving a smooth even surface, as opposed to ribbed in which some of the wales appear on the back of the fabric and some on the front, giving a distinctly lined or ribbed surface. Ribbing is produced by two sets of needles operating simultaneously, one set forming the loops which appear on the inner surface of the fabric and the other set forming the loops on the outer surface; by arranging the needles any desired grouping of ribs may be effected.

---

[2] See Cotton Hosiery, p. 8.

When some needles are left out of the machine a thinner and more open fabric is produced. If a sufficient number are omitted the resultant product will be gauze. Either a ribbed or a flat fabric may be napped by passing it over a special machine, which raises the fiber. Fleece lining is obtained by the introduction of a separate yarn, usually loosely spun, on the back of the material and the application of the napping process which will act more directly on this extra yarn.

Competing articles.—So popular has men's "athletic" underwear made from woven material become that it is now a very definite competitor of knit goods. In women's lines the increasing vogue for silk—glove silk, crêpe de chine, habutai—has somewhat retarded the development of cotton knit goods.

Other wearing apparel.—Besides underwear, bathing suits, sweaters, and sometimes toques and scarfs are knit of cotton. No statistics for any of these articles are given separately as cotton products, hence only general conclusions can be made in this discussion concerning wearing apparel other than underwear. Cotton goods in these articles are usually cheap grades, as the better class of goods are made of wool or silk.

DOMESTIC PRODUCTION.

Materials.—Cotton yarn in all grades, carded, combed, mercerized, is used by the knit-underwear industry. Most of the domestic underwear is made from yarns ranging from 8's to 80's, whereas that imported prior to 1914 was usually in yarn of finer counts; in the last few years imports of coarser goods from Japan have increased. Philadelphia is the principal market for knitting yarns, but many southern mills buy their yarns locally and, as in the hosiery industry, large mills frequently have their own spinning departments. Very little imported cotton yarn is used. In 1914 the hosiery and underwear industries imported 1,006,176 pounds of cotton yarn and in 1918, 272,238 pounds,[3] a very small part of the total used which approximates 300,000,000 pounds.

Linen, or vegetable fiber, other than cotton, is used in the knit-underwear industry to a very limited extent. Linen yarn is not so well adapted to the knitting process as are cotton, wool, and silk, being harsher and less pliable. The quantity of linen, jute, and other unspecified fibers, used in the entire knit goods industry in census years was as follows: 116,160 pounds in 1899; 62,617 pounds in 1904; 241,754 pounds in 1909; and 70,278 pounds in 1914. The quantity of these fibers used in 1914 amounted to only 0.02 per cent of the material used by the entire knit-goods industry. Separate figures for yarn consumed by the underwear industry are not available.

Besides yarn, the underwear industry requires finishings such as buttons, bandings, tapes, ribbons, laces. These, however, form a small part of the material cost.

Cost of production.—A report of the Department of Commerce published in 1915 [4] shows the relation of the various items entering

[3] Cotton yarn, Tariff Information Series No. 12.
[4] The Knit-Underwear Industry, Misc. Series, No. 32.

into the cost of knit-underwear manufacture. The summary table[5] shows the total manufacturing cost divided as follows:

	Group of mills in—		
	New York and Massachusetts.	Pennsylvania and Ohio.	Maryland, North Carolina, and Tennessee.
	Per cent.	*Per cent.*	*Per cent.*
Raw material	64.97	67.83	72.16
Direct labor	24.11	20.34	14.37
Indirect labor	3.40	3.71	5.89
Overhead	7.52	8.12	7.58
Total	100.00	100.00	100.00

These proportions may vary somewhat at the present time, but in general they hold true.

It is significant that northern mills show a proportionately higher labor cost than southern mills. This results partly from higher wage rates but largely from the fact that more expensive grades of goods are made in northern mills, and although the material costs on such goods are actually more, relatively they are less, because the greater skill required in all processes of manufacture gives a labor cost which more than offsets the amount paid for material. Even in a given locality the wages of knitters vary according to the fineness of the yarn on which they work, and, moreover, production on a fine-gauge machine is slower than on one of coarse gauge; thus two elements tend to increase the cost of labor per unit of output proportionately to the fineness of the material.

Organization.—It will be seen from the above discussion of standardization that quantity production would be more profitable than production on a small scale. So it is that there are fewer small underwear mills than small hosiery mills. (See Cotton hosiery, p. 13).

The following table shows that the cotton-underwear industry, like the cotton-hosiery industry, is more or less specialized, only a small proportion of the total output being produced in mills that are not primarily underwear mills:

TABLE 2.—*Production of cotton knit underwear, by type of establishments.*

Made in—	Quantity.	Per cent of total quantity.	Value.	Per cent of total value.
	Dozen pairs.			
Underwear mills	21,406,374	96.54	$137,966,960	96.02
Fancy knit-goods mills	418,931	1.89	3,418,126	2.38
Knitted-cloth mills	349,174	1.57	2,301,333	1.60
Total	22,174,479	100.00	143,687,019	100.00

The machines used in making underwear are generally the large circular machines on which fabric for other purposes may be made. Hence it so happens that the value of the knit fabric for other pur-

[5] Ibid., Table 32, p. 74, gives percentages based on total cost of goods manufactured and selling expense. The figures given here are derived from the same table, but based on the cost of manufacturing only.

poses may be greater than the value of the underwear produced by a mill.

Equipment.—The equipment in the underwear industry includes a number of expensive machines. These are practically all the result of American ingenuity, and all types are made in this country. The circular underwear machine has undergone little change or improvement in the last 20 years, but the electric cutting, the seaming, and the finishing machines which play an important part in the manufacture of cut goods have been perfected both in facility of operation and in the results accomplished.

Methods of production.—Standardization in the underwear industry while perhaps not essential has been an important element of success in this country. After the material is knit and the garment cut, the seaming and finishing processes are numerous and while mechanical are not automatic. This necessitates frequent handling of the garment between the cutting and the shipping departments, hence the greatest individual efficiency and the highest productive capacity are attained by subdivision of labor. A girl masters thoroughly the type of machine she is required to operate, and working always on one part of the garment handles it with greater dexterity. One girl will attach the cuffs only, another sews the shoulder seams, another the body seams, and so on until all the operations are completed. The same kinds of seams are not used for all parts of the garment, and even though the character of the seam may be the same, various attachments are added to the machines to facilitate manipulation of the article. It may be seen that standardization is highly desirable, partly because of the machinery, but more largely because of the increased speed of the operative, who doing the same piece of work day after day, becomes increasingly efficient. The wages are on a piecework basis, so that increased efficiency accrues immediate benefit to the operative. This does not always work out in practical application because a very general increased efficiency may be followed by a lowering of piecework rates.

Foreign processes on a given grade of goods are not essentially different from the American, but more full-fashioned goods are made in Europe than in the United States. In France, in some cases, the industry frequently has two phases, the knitting of the tubular fabric in one establishment and the manufacture of the garment in another.

Geographical distribution.—New York is the leading State in the manufacture of cotton underwear. The principal centers are Utica and Amsterdam. Other States which have large cotton underwear mills are North Carolina, Georgia, Tennessee, and Pennsylvania.

Domestic production and consumption.—The cotton-underwear industry in 1919 produced 22,174,479 dozen garments, valued at $143,687,019, and in 1914, 25,204,628 dozen garments, valued at $68,715,752. The decrease in quantity is not so great as these figures seem to indicate, because the 1919 production included 7,518,516 dozen combination suits, the 1914 only 5,468,730 dozen. There was such a large production in 1918 by reason of the demands for the Army and Navy that a considerable surplus probably remained to be absorbed in 1919.

Figures compiled by the War Industries Board show that 26,219,375 dozen shirts and drawers (about 8,000,000 dozen for the Government) and 8,744,425 dozen union suits, a total of 34,963,800 dozen garments, were made in 1918.

From 1899 to 1914 the output of the industry increased about 100 per cent, while the value of the output increased almost 200 per cent. The increase in value of output in 1914 over 1909 was 15 per cent. The combination suit is steadily gaining in popularity, showing an increase of 167 per cent in quantity over 1909, whereas there was a decrease of nearly 13 per cent in the number of shirts and drawers. The quantity of union suits produced represented 8 per cent of the total cotton underwear in 1909, 22 per cent in 1914, and, according to the War Industries Board figures, 25 per cent in 1918. Because of the prevalence of modern heating systems, lighter weight goods are required. This may be one reason why woven goods are competing strongly with knit goods.

Unlike cotton hosiery, cotton underwear has increased relatively as well as actually—representing 59 per cent of the entire value of the underwear industry in 1899, 70 per cent in 1904, 71 per cent in 1909, and 74 per cent in 1914, gaining somewhat in favor over wool mixed.

Domestic exports.—American underwear manufacturers profited especially in export markets by their foreign competitors' disadvantage during the war. In 1914 exports of all cotton knit goods, which included underwear, were valued at $2,546,822; in 1918, the first year stated separately, exports of cotton knit underwear alone were valued at $2,602,293.

In the calendar year 1920 they amounted to $14,067,839. Thus foreign trade fell to a value of $3,602,493 in 1921, which, however, was still above the pre-war level. The markets for cotton underwear, as for cotton hosiery, are scattered through practically all of the countries of the world. The United Kingdom, Australia, Cuba, and Argentina were the most important consumers of American goods in 1920, the trade with each of which amounted to over $1,000,000. The decline in American export trade is probably due entirely to the condition of business the world over, as there has not been sufficiently aggressive foreign competition to drive American goods out of these markets.

Few manufacturers of women's underwear find the export trade profitable, because the character, quality, and style of garment demanded for the export trade are altogether different from that made for the American market. This is less true of men's underwear.

FOREIGN PRODUCTION.

Besides the United States, the leading countries manufacturing knit cotton underwear are Switzerland, Germany, France, England, and Japan. The Swiss make a fine grade specially for the export trade for which they find a good market in England and the British colonies and even in the United States. In 1913 Swiss exports of cotton knit goods other than gloves and hosiery were valued at $597,142 (franc = $0.193); by 1919 exports had increased in value nearly 700 per cent, equaling $4,796,992 [6] (converted at the same rate). Of course, the increase in the volume of trade was not actually what these figures on the surface indicate, because prices were higher and exchange was variable in 1919. The maximum quantity was exported in 1917, but because of the difficulty of trading with Germany, which previously received large amounts of cotton goods,

[6] L'Exportateur Suisse (periodical), March, 1920.

and the import restrictions in England, the Swiss exports of cotton knit goods were less in 1918 and in 1919 than in 1917.

Total German exports of cotton knit underwear prior to the war were very much greater than exports from Switzerland, amounting to $9,912,700 in 1913; Great Britain was the most important market for the German export trade; only a small proportion went to the United States. Apparently the German cotton knit underwear industry in the spring of 1922 had not attained its pre-war status, judging from the following statistics:

TABLE 36.—*German exports of cotton knit underwear.*

[1] No statistics available for first 4 months of 1921. [2] Included in "other countries."

Exports of cotton knit goods from the United Kingdom have not varied greatly, averaging about $2,000,000 annually from 1913 to 1918. Japan built up an extensive trade in cotton knit underwear during the war, but recent recessions in foreign markets indicate that the Japanese industry will lack sufficient stability to compete with Europe and America. Like the cotton hosiery made in Japan, the underwear is said to be of inferior grade and very imperfect cut and finish.

IMPORTS.

In the last census year, 1914, imports of cotton knit goods, exclusive of hosiery and gloves, amounted to 106,251 dozen, as compared with a domestic production of 25,204,628 dozen. The value of the imported articles was $341,983, which was only 0.5 per cent of the value of cotton underwear produced in this country. According to the War Industries Board figures for domestic production, imports were only one-tenth of 1 per cent of the American output in 1918. The greatest amount imported in the last three decades was 259,114 dozen, valued at $810,033, in 1907. This value was exceeded in 1919, although the quantity was about one-third less, the unit value in 1907 being $3.13 per dozen, and in 1919 $6.78. Imports for 1920, 24,329 dozen, valued at $187,645, were the smallest in the last 30 years. Since 1891 imports have averaged between 150,000 and 200,000 dozen. It is interesting to note that imports tended to increase under the act of 1897 (1898–1909) and to decrease under the act of 1909 (1910–1913), although the classifications and rates were identical under the two acts. (Tables 6 to 8, pp. 68 to 72.)

Imports by countries (Table 5, p. 67) from 1914 to 1918 include gloves. As the imports of gloves (judging by imports for consumption) were three or four times the imports of other cotton knit goods, figures for 1914 and succeeding years are not comparable with figures for previous years.

Practically all of these gloves prior to the war came from Germany, hence the relation of each country to the total is decidedly altered by their inclusion in cotton knit goods statistics. Prior to the act of 1913 about one-third of the cotton knit goods, consisting largely of underwear, came from Germany, one-third from Switzerland, and practically all of the remainder from France, England, and Denmark, in the order named. Since 1914 the proportion of goods from Japan has increased, but the total quantity has not been large.

One large American underwear mill could produce in a few months as many knit cotton garments as are imported into this country in one year.

PRICES.

Because of the great variety of knitted underwear and the fact that there are no regular market quotations, it is practically impossible to follow a given line of goods over a series of years. Price trend is about all that can be indicated and that is not uniform in all grades of goods. Men's balbriggans, which according to the War Industries Board price study (Table 11, p. 73) were $3.25 per dozen wholesale in 1913 and $7.0625 in 1918, are now offered at the 1913 price. An extract from the official organ of the National Hosiery and Underwear Manufacturers' Association shows price fluctuations within the last year:[1]

> A line of union suits which went on the market last year for the spring, 1920, at $17 a dozen and during the season advanced to $22, is priced $12 for spring, 1921. The price is based on reduced operating costs—wage reductions, increased working hours, cotton bought at the lowest price in several years, and with the mill running to capacity, minimum overhead and the promise of maximum efficiency.

The relation of present (January, 1921) to pre-war price is indicated by the following from the same source:

> In each of several lines of underwear the prices for spring are approximately 50 per cent above the high pre-war average. A knitted garment priced $8 a dozen in 1915 and sold for some time at or about that figure is priced $12 for next spring. It formerly was made from carded yarn, whereas now it is of combed, so that relatively the price is not 50 per cent higher than in 1915.

TARIFF HISTORY.

The act of 1883 (par. 323) imposed a duty of 40 per cent ad valorem upon shirts and drawers fashioned, narrowed, or shaped by knitting machines or frames or knit by hand. Shirts and drawers not otherwise provided for were dutiable at 35 per cent ad valorem (par. 322).

The act of 1890 divided cotton knit underwear into five value classifications bearing compound rates of duty on all except the lowest, which was 35 per cent ad valorem. These rates were the highest in tariff history on this class of goods, averaging for the three full years under this act, 1892–1894, an actual equivalent ad valorem duty of 68 per cent.

In accordance with the general policy of the act of 1894 these rates were reduced and the classifications thrown into one, dutiable at 50 per cent ad valorem. This did not have the effect of stimulat-

[1] Knit Goods Bulletin, December, 1920, p. 292.

ing imports, which in the highest year were 168,804 dozen articles as compared with an importation of 194,083 dozen articles in 1893 under the higher rates of the act of 1890.

The act of 1897 restored the value classifications and the compound rates, although these were somewhat lower than in the act of 1890. The description was altered, making the paragraph possibly slightly more inclusive. Again the change in rates had apparently little effect upon imports, which continued about the same for several years and increased (with rates from 10 to 12 per cent above the preceding act) from 1902 to 1908. The greatest quantity imported in any year was 259,114 dozen in 1907. The provisions of the act of 1909 were identical with those of the act of 1897, but imports steadily decreased, amounting to only 105,160 dozen in 1912 and 87,599 dozen in 1913, which shows that the domestic industry with an output of over 25,000,000 dozen garments in 1914 held a secure position in the home market.

It is interesting to note the effect which the various classifications of these acts had upon the character of imports.[8] The lowest classification, viz, that of "not over $1.50" value per dozen articles was dutiable at a minimum equivalent ad valorem rate of 55 per cent. Imports under that class were comparatively small, from 12 to 15 per cent of the total, probably the strength of domestic manufacturers in the very cheap lines precluding competition.

In the next class, namely, that valued at over $1.50 to $3 per dozen, the equivalent ad valorem rates range from the highest, 88 per cent ($1.10+15 per cent on a value of $1.50), to almost the lowest, 52 per cent ($1.10+15 per cent on a value of $3), under the paragraph. Imports under this classification are the largest, representing over 50 per cent of the total quantity, and quite naturally the unit values more nearly approach the upper limit. (Table 7, p. 69.) The rates under the next classification ($3 to $5) might vary from 50 per cent to 75 per cent. This class was second in importance, averaging 25 per cent of the total imports. Although the rates tend to diminish above the $5 value, imports in these classes are relatively small because of the narrower market for high-priced goods.

The act of 1913 about halved the average rates under the two last acts, levying a flat rate of 30 per cent without value classifications. Imports under this act have never equaled the lowest years under the acts of 1897 and 1909 (except the one year 1913). Even in 1920, a year which showed increased imports in many lines, only 24,329

[8] The following outline shows the possible range of rates in each classification of the acts of 1897 and 1909:

Rate of duty.	Value.	Equivalent rates.	
		Ad valorem.	Specific.
	Dozen.	*Per cent.*	*Dozen.*
$0.60 plus 15 per cent	$1.50	55	$0.82
$1.10 plus 15 per cent	$1.50–3.00	88	1.33
		52	1.55
$1.50 plus 25 per cent	3.00–5.00	75	2.25
		55	2.75
$1.75 plus 35 per cent	5.00–7.00	70	3.50
		60	4.20
$2.25 plus 35 per cent	7.00–15.00	67	4.92
		50	7.50
50 per cent	15.00	50	7.50

dozen cotton knitted undergarments of foreign origin were landed in this country.

The annual revenue received from this item has never been as much as one-half million dollars.

The duty on manufactures of long-staple cotton under the emergency tariff act of May 27, 1921, applied to underwear made of this type of cotton. According to the records, while that act was enforced a very small proportion of the imported underwear was made of long-staple cotton.

The act of 1922 levies a flat rate of 45 per cent ad valorem on cotton knit underwear and wearing apparel other than gloves and hosiery.

COMPETITIVE CONDITIONS.

It is evident that there is little foreign competition, considering the cotton knit wearing apparel industry as a whole, since imports amount to only about one-half of 1 per cent of the domestic production. But these imports are more or less of one class of goods—fine underwear—and do, therefore, compete to some extent with domestic manufactures of the same grade.

The American knitting industry is independent of foreign markets for its yarns.

> Even in 1914 the imports constituted only a fraction of 1 per cent of the cotton yarns consumed by the domestic knitting industry, and local yarns had so steadily improved that there was no very strong reason for continuing imports except on the high counts or for special purposes.[9]

In fact, it is quite possible that American manufacturers have an advantage as regards raw material. The study quoted above states:[10]

> German spinners could not compete in the American market either with the domestic coarse yarns or with the fine special yarns from England, and their sales in the United States * * * were mainly due to special finish—fast dyeing, high polishing, or careful mercerizing.

This, of course, does not necessarily indicate that the German yarn-consuming industries must import their material, but it seems evident that there can not be much expansion in the industry without importation. Switzerland is in somewhat the same position. England, which manufactures the bulk of the fine yarns of commerce, is not a serious competitor in cotton knit underwear.

The condition which most adversely affects the American manufacturer is the difference in wage rates here and abroad. That, however, is in great measure overcome by the American industrial system. By standardization of product and division of labor the total production and the efficiency of the individual laborer is increased. This militates to some extent against the success of the American manufacturer in the export trade, because whereas the standardized article is well received in the domestic market, the foreign trade requires a variety of product, different in style, weight, quality, and finish not only to meet differences in climate, but to suit the popular taste in each locality.

TABLE 12.—*Cotton knit wearing apparel (except hosiery and gloves—Rates of duty—* Continued.

Act of—	Par.	Tariff classification or description.	Rate of duty.
1913....	261	Shirts and drawers, pants, vests, union suits, combination suits, tights, sweaters, corset covers, and all underwear and wearing apparel of every description, not specially provided for in this section, made wholly or in part on knitting machines or frames, or knit by hand, finished or unfinished, not including such as are trimmed with lace, imitation lace or crochet or as are embroidered and not including stockings, hose and half hose, composed of cotton or other vegetable fiber.	30 per centum ad valorem
1921....	16	Cotton having a staple of 1⅛ inches or more in length.....	7 cents per pound.
	17	Manufactures of which cotton of the kind provided for in paragraph 16 is the component material of chief value.	7 cents per pound, in addition to the rates of duty imposed thereon by existing law.
1922....	917	Underwear and all other wearing apparel of every description, finished or unfinished, composed of cotton or other vegetable fiber, made wholly or in part on knitting machines, or knit by hand, and not specially provided for.	45 per centum ad valorem.

COURT AND TREASURY DECISIONS.

The provision in paragraph 339 of the act of 1897 for wearing apparel in part of lace was held to be more specific in reference to cotton neckwear composed in part of lace than the provision in paragraph 314 for neckties or neckwear composed of cotton. (Goldenberg *v.* United States, 130 Fed. 108, of 1904; petition for certiorari denied, 195 U. S. 634.)

Cotton knit shawls, returned by the appraiser as "imitation cotton lace wearing apparel," were declared not to be made wholly or in part of imitation lace within paragraph 339 of the act of 1897 but were held to be dutiable under paragraph 314 which provided for wearing apparel composed of cotton or other vegetable fiber or of which cotton or other vegetable fiber was the component material of chief value, made up or manufactured wholly or in part by the tailor, seamstress, or manufacturer. (G. A. 6040, T. D. 26369, of 1905.) In Abstract 34284 T. D. 34000, of 1913, cotton lace shawls were held to be dutiable as cotton lace wearing apparel under paragraph 349 of the act of 1909 rather than as wearing apparel of cotton under paragraph 324. Knit scarfs, composed of cotton and lace, cotton chief value, made on knitting machines or frames were, however, held dutiable as cotton knit wearing apparel under paragraph 261 of the act of 1913 rather than under the provision in paragraph 358 for "wearing apparel, and all other articles or fabrics made wholly or in part of lace or of imitation lace of any kind." (G. A. 7775, T. D. 35715, of 1915. But in a later case brought by the same importers, upon proof of commercial designation, merchandise identical with that passed upon in T. D. 35715, *supra*, was held to be properly dutiable under the provision in paragraph 358 of the act of 1913 for "wearing apparel, and all other articles or fabrics made wholly or in part of lace or of imitation lace of any kind." (G. A. 7947, T. D. 36596 modifying G. A. 7775, T. D. 35715, *supra*.)

PREFACE.

This is one of a series of Tariff Information Surveys prepared by the United States Tariff Commission and transmitted to the Committee on Ways and Means. The series covers all of the articles and commodities provided for in the tariff act of October 3, 1913, and others not specifically provided for. It is arranged in the numerical order of paragraphs of that act.

In some cases two or more paragraphs have been combined in one pamphlet. In doing this industrial relationship of the articles has been followed when possible. In those instances where a paragraph has been treated under a preceding paragraph of the tariff act reference is made to this fact at the point where the paragraph appears in numerical order. Where one grade of an article is dutiable and another grade of the same article is on the free list, the article is discussed under the dutiable paragraph, which appears first in numerical order in the tariff act. In certain instances articles of close industrial relationship and which occur in separate paragraphs of the tariff act have been combined under one paragraph for convenience of discussion. Reference is made to this fact at the point where the commodities would naturally occur in numerical order.

The first pamphlet in the series is an "Introduction and index," which contains:

1. An introductory chapter discussing the scope of the series and the general method of treatment.
2. An alphabetical index of the articles provided for in the tariff act of 1913, showing the paragraph of the act in which the article was provided for and, if discussed under a different paragraph, the number of such paragraph.
3. A list of the pamphlets in the series, showing the paragraphs and articles included in each pamphlet.

Thus by use of this "Introduction and index" the exact location of the discussion relating to a given article or commodity can be ascertained.

In the preparation of this report the Tariff Commission has had the services of Evelina P. Kean, of the textile division of the commission's staff, and of others.

COTTON WEARING APPAREL.

TARIFF ACT OF OCTOBER 3, 1913.

[Text of Schedule I, providing for cotton wearing apparel, except knit goods, not ornamented with lace or embroidery.]

Par. 255. Handkerchiefs or mufflers composed of cotton, not specially provided for in this section, whether finished or unfinished, not hemmed, 25 per centum ad valorem; hemmed, or hemstitched, 30 per centum ad valorem.

Par. 256. Clothing, ready-made, and articles of wearing apparel of every description, composed of cotton or other vegetable fiber, or of which cotton or other vegetable fiber is the component material of chief value, or of cotton or other vegetable fiber and india rubber, made up or manufactured, wholly or in part, by the tailor, seamstress, or manufacturer, and not otherwise specially provided for in this section, 30 per centum ad valorem; shirt collars and cuffs of cotton, not specially provided for in this section, 30 per centum ad valorem.

PLAIN COTTON HANDKERCHIEFS.

SUMMARY.

Plain cotton handkerchiefs constitute probably three-fourths of the total quantity of handkerchiefs produced in the United States. Although it is not entirely a specialized industry, the bulk of the output is by large, well-organized establishments making only handkerchiefs. These are located mainly in New York City, New Jersey, and Pennsylvania.

The value of the domestic production of plain cotton handkerchiefs in 1914 was estimated at about $10,000,000. The valu e of the production in 1920 was probably three times this amount, the increase being due mainly to the higher level of prices, but partly to the larger production and consumption of plain cotton handkerchiefs resulting from the scarcity and relatively higher prices of linen handkerchiefs.

Imports of plain cotton handkerchiefs were very small prior to the fiscal year 1914, when they increased to $112,499. Imports in the calendar year 1920 were abnormally large, being valued at $1,633,769. This record import was due to trade conditions in the aftermath of the war period, but did not amount to as much as 5 per cent of the domestic production.

GENERAL INFORMATION.

Handkerchiefs were provided for in the act of 1913 as follows:

		Per cent ad valorem.
Par. 255. Cotton:		
	Plain, unhemmed	25
	Plain, hemmed or hemstitched	30
Par. 282. Flax, hemp, or ramie:		
	Plain, unhemmed or hemmed	35
	Plain, hemstitched, imitation hemstitched, revered, or with drawn threads	40

	Per cent ad valorem.
Par. 315. Silk:	
Plain, unhemmed or hemmed	60
Plain, hemstitched, imitation hemstitched, revered, or having drawn threads	50
Par. 358. Of any material:	
Embroidered, tambooned, appliqued, scalloped, or made wholly or in part of lace or imitation lace	60

Relative imports under these four paragraphs of the 1913 act varied from year to year, but as a rule the largest proportion of the handkerchiefs imported entered under paragraph 358, followed by 282 and then 315, with 255 ranking as the least important so far as regarded importations. This is clearly shown by the following table:

Handkerchiefs—Imports for consumption.

	Plain.			Ornamented with lace or embroidery.			Total.
	Cotton.	Linen.	Silk.	Cotton.	Linen.	Silk.	
Fiscal year:							
1911	$46,128	$294,627	$25,222	$468,422	$2,285,325	$343,579	$3,463,195

[1] Includes $2,248, for manufacture in bonded warehouse and export.

DESCRIPTION.

Paragraph 255 of the act of 1913 covered the staple article that constitutes the bulk of the handkerchief trade, the plain hemmed or hemstitched cotton handkerchief which is made in the United States in large quantities. To prevent the evasion of duty on goods but one step removed from the finished article, there was special provision in this paragraph for unhemmed handkerchiefs, this covering cloth cut to handkerchief size or goods in the piece which are obviously intended by reason of printing, marks in the weaving, or otherwise, for making into handkerchiefs.

All grades of light-weight cotton cloth, from ordinary print cloth up to the finest combed lawn, are used for making handkerchiefs. These are of varied styles and sizes; women's handkerchiefs are made up to 15 inches square whereas men's handkerchiefs are mainly 18 to 23 inches square. Mufflers, also mentioned in paragraph 255, are large kerchiefs, used ordinarily to protect the throat or head. They present no distinct problem apart from handkerchiefs and in the volume of trade are of slight importance.

DOMESTIC PRODUCTION.

Materials.—Cotton cloth used in the production of handkerchiefs includes print cloths, made of 28s to 42s yarns, longcloths made of 40s to 60s yarns, and combed lawn made of 60s to 110s, or finer, yarns. In the first two classes the material is almost invariably domestic, as satisfactory cloths of this type can be obtained here at prices that are usually lower than those at which similar goods can be landed from abroad. The combed lawns used are partly domestic and partly imported; part of the import is due to lower prices and part to superior quality or the fact that cloths of the desired fineness can not be obtained in this country.

The following particulars, of typical cotton cloths, in the gray, largely used in making handkerchiefs, are supplied by leading manufacturers:

Width in inches.	Yards per pound.	Ends and picks per square inch.	Total threads per square inch.	Official average yarn count.
Carded:				
39	4.25	72 by 76	148	29.2

Methods of production.—The handkerchief manufacturers buy their cloth, which is therefore the "raw material" of the handkerchief industry. After being bleached, and in some cases dyed or printed, the cloth is cut and the edges are hemmed or hemstitched on machines. The handkerchiefs are then ironed, folded, boxed, and cased. Handkerchiefs may be woven as such on the loom but this method is not in general use in the United States.

The following description of handkerchief manufacture is given by a representative of the industry:[1]

The manufacture of cotton handkerchiefs presents no special difficulties and those with either color or silk borders are easily made, providing due attention is paid to a few features and the calculations therefor are taken into consideration. The actual loom production may be lowered slightly and in some cases a larger number of harnesses may be required than for ordinary plain goods.

[1] Kaskel, J. S.: Southern Textile Bulletin, July 27, 1922.

The construction for most of the cloths used for this class of merchandise is a plain lawn. The cloth is usually within a range of from 7 to 8½ yards per pound; the warp is usually about 60 singles; the filling between 90 and 105 singles. Naturally there are variations from these figures, but on the whole that is a reasonable range and the most popular one.

Handkerchief cloth is woven in different widths with due regard being paid to such breadth which will permit of its being cut up by the handkerchief manufacturer as will be the most economical for his work. * * * Some of the best widths in which these goods are made are 36, 39, 40, and 46 inches. The advantages of these will be readily grasped by making the handkerchiefs a size to correspond which will produce the least waste. Thus a 36-inch cloth will give three handkerchiefs each one measuring 12 inches wide and 11.75 inches long. The 39-inch width will permit the cutting of two of the dimension of 19.5 inches wide and 19 inches long. The 40-inch width will give two which are each 20 inches wide and 19.5 inches long. The 46-inch width is good for four handkerchiefs each of which are 11.5 inches wide and 11.25 long.

Handkerchiefs are almost always square and it probably has been already noted by the reader that there is a slight difference between the length and width of each handkerchief in the above calculation. This is done purposely as the cloth in finishing will extend in the length and contract in the width as many cotton fabrics. do. This extension and contraction balances and will make the handkerchief square, but the advantages remain with the manufacturer as he will be enabled to obtain a few more pieces out of the cut.

In weaving cloth for this purpose we always provide a mark for the cutter both in the width and in the length. This is done to facilitate his work. To mark it in the direction of the warp we often leave two or three dents empty. This is the particular system followed on gray goods, but in color work that would not be sufficiently clear and distinct, so there we draw in one gray cord which is visible. When a gray cord is used we have found that a 2/20s is large enough and this should be given one full dent.

To make a shearing or cutting mark in the direction of the filling we shoot in several picks in one shed. This raised cord effect is a very good and easily apparent line to guide the cutting. In this respect it is most essential that great care and attention be given to the distance between the cutting marks otherwise losses will be created, because the sizes must be exact.

Handkerchiefs in the course of their manufacture are folded so that the corners are turned in and it is absolutely imperative that these four corners meet in the center. If they do not, the handkerchief is cut into shape that they will. If the weaving of the cloth and the placing of the shearing marks therein are not done carefully there will be a waste. This must be avoided.

The hemming or hemstitching of handkerchiefs is work well adapted to female labor; the material handled is light and the operation involves the use of only the ordinary sewing machine, or similar machines with hemstitching attachments, either of which can be run by power. By far the larger part of the wage earners are women, the latest inclusive records showing that on December 15, 1914, there were employed in the handkerchief industry 7,272 women as against 1,064 men, or roughly in the proportion of 7 to 1.

Organization.—Few manufacturers confine themselves to handkerchiefs of any one type or material. The majority use both cotton and linen cloths, and produce both men's and women's handkerchiefs, plain and ornamented. Moreover, the manufacture of handkerchiefs is not entirely a specialized industry, sometimes being reported as a subsidiary of wearing apparel manufacture.

The bulk of the output is made under large-scale factory conditions, although a not inconsiderable proportion is made in small shops and by individuals working on contract. The handkerchief industry has not been separately reported by the Census Bureau, but a study of the original schedules for 1914 showed that approximately 80 per cent of the total domestic product, including ornamented handkerchiefs, was put on the market by 49 manufacturers who had the handkerchiefs made up and finished in their own plants. The remaining 20

per cent was produced by about 75 small concerns, which worked by contract on materials supplied them by others; their output was largely of handkerchiefs embroidered or otherwise ornamented. Over half of the total handkerchiefs was produced by six firms having a combined output of more than $7,500,000 annually. Four of these produced more than a million dollars' worth each, and two produced over a half million dollars' worth each. A total of 27 other manufacturers reported individual outputs ranging between $50,000 and $500,000 annually.

A considerable number of establishments making handkerchiefs have small working forces, but the larger factories employ several hundred each. The largest plant devoted entirely to handkerchiefs employed during 1914 an average of nearly 1,400 workers.

Geographical distribution.—The handkerchief industry is largely localized in the northeastern States, with New York as the main distributing center. Of the 25 largest plants, 11 are in New Jersey, and 8 of these in Passaic. A number of important establishments are located in Pennsylvania, several in Rhode Island, and a considerable number in and around New York City.

Domestic production.—Cotton and linen handkerchiefs, plain and embroidered, are usually made in the same establishment; this renders it difficult to treat the manufacture of cotton handkerchiefs separately. The value of the plain cotton handkerchiefs produced in 1914 was estimated at about $10,000,000, or about two-thirds of the total for all handkerchiefs.[2] Considering the lower average value of the cotton article, it is probable that plain cotton handkerchiefs constitute at least three-fourths of the number of handkerchiefs produced annually in the United States.

Domestic exports.—Handkerchiefs were not separately stated in export statistics of the United States prior to January, 1922. In the first six months of 1922, exports of cotton handkerchiefs amounted to 144,797 dozen, valued at $98,739. Export trade in handkerchiefs, as in most other manufactures of cotton, has increased during the last few years. An indication is afforded by Canadian statistics, which record importations of American cotton handkerchiefs valued at $175,460 in 1920, as against only $6,111 in 1914, fiscal years ending March 21.

FOREIGN PRODUCTION.

There are no statistics as to the volume of foreign production of cotton handkerchiefs. As the manufacture of handkerchiefs is largely a cutting-up trade, requiring little skill, undoubtedly most countries supply the great bulk of their domestic needs of this staple article of convenience out of the piece goods that they weave or import. In the greater number of instances, cotton handkerchiefs are not separately recorded in import and export statistics.

Such partial data as are available indicate that the United Kingdom is the main exporter, supplying all grades, from the gaudy bandanna to handkerchiefs of the finest quality. The cotton cloth is, as a rule, woven in Great Britain but Belfast is the main export center, being

[2] Derived from a study of the original schedules prepared by manufacturers for the 1914 census and verified by statements at the tariff hearings. As the year 1914 was a period of depression and reduced operations in the handkerchief trade, the normal output was probably larger than indicated; in recent years higher prices alone would greatly increase the total value.

favored because of the excellence of its bleaching, the cheapness of home labor available for initialing or otherwise ornamenting the article, and the fact that it is also the main export center for linen handkerchiefs and therefore accustomed to putting up handkerchiefs in any style required. The cotton manufacturing countries of the Continent, such as Germany, Austria, Switzerland, France, and Italy, export in smaller quantities, as also do Japan, and recently, the United States. The Swiss handkerchiefs exported are mainly embroidered; French handkerchiefs are mainly of fine quality and largely of those ornamented with lace.

IMPORTS.

Prior to the act of 1897 imports of cotton handkerchiefs were not separately recorded, being included in records of importations of handkerchiefs made of cotton "or other vegetable fiber." In the 23 fiscal years 1898 to 1920, inclusive, imports of plain cotton handkerchiefs averaged $175,748 annually.

In the period covered by the acts of 1897 and 1909, with no change in the wording descriptive of handkerchiefs brought in, the equivalent ad valorem rate of duty averaged 52.46 per cent on actual imports. Imports ranged from a high of $147,437 in 1899 to a low of $39,964 in 1913. Under the act of 1913, in the period from October 4, 1913, to June 30, 1920, inclusive, the ad valorem rate of duty averaged 29.10 per cent. Imports under the act of 1913 were more substantial, ranging from a low of $120,153 in the fiscal year 1915 to a high of $1,633,769 in the calendar year 1920. If the value of the domestic production of plain cotton handkerchiefs was $[illegible] in 1914 it must have been two or three times as much in 1920, and the record import in 1920 was therefore less than 5 per cent of the domestic production.

The finished handkerchief, hemmed or hemstitched, has always made up the bulk of the import trade in plain cotton handkerchiefs. Importations of handkerchiefs in the piece, or handkerchiefs cut but not hemmed, constituted in the highest year less than one-ninth of the total imports under paragraph 255 of the act of 1913, and prior to 1916 were practically negligible.

Imports of plain cotton handkerchiefs, dutiable under paragraph 255, were usually much less important than imports of fancy cotton handkerchiefs, adorned with embroidery, lace, or otherwise, dutiable under paragraph 358 of the act of 1913 at 60 per cent ad valorem. Imports in the fiscal year 1920 were exceptional in that plain cotton handkerchiefs were slightly in excess of fancy cotton handkerchiefs.

The increase in imports of plain cotton handkerchiefs to more than a million dollars in 1920 was due to various causes. During the calendar year 1919 prices of cotton manufactures in the United States increased greatly, whereas European prices rose more slowly; the divergence became so great in the fall of 1919 that, aided by the drop in the exchange value of the pound sterling which increased the purchasing power of the American dollar, importing became unusually profitable. This greatly stimulated the purchase abroad of cotton cloth and of articles made therefrom. The fact that British prices were also rising quickened buying, not only because of a desire to take advantage of prevailing prices but because of the saving in customs dues under an ad valorem duty by importing before prices could

rise further. This flood of buying orders lasted until March, 1920, by which time British prices had risen to more nearly their normal relation to the American. Another factor that stimulated imports of plain cotton handkerchiefs was the scarcity of plain linen handkerchiefs, arising mainly from the scarcity and high price of fine linen from which to make such handkerchiefs.

Imports of plain cotton handkerchiefs are almost entirely from the United Kingdom and Switzerland, although there are small and more or less sporadic imports from a few other countries.

TARIFF HISTORY.

Under the act of 1890 cotton handkerchiefs unhemmed or hemmed were dutiable at 50 per cent ad valorem, if hemstitched, at 60 per cent ad valorem; under the act of 1894 these rates were reduced to 40 per cent ad valorem.

Under the act of 1897 cotton handkerchiefs unhemmed or hemmed were dutiable at the same rate as the cloth of which composed, but with a proviso for a minimum rate of 45 per cent ad valorem; if hemstitched or imitation hemstitched or revered they were dutiable at a differential of 10 per cent ad valorem above the cloth duty, but with a proviso for a minimum rate of 55 per cent ad valorem. The 1897 provisions were reenacted without verbal change in 1909. There was, however, some inherent difference inasmuch as the cloth schedule, which formed the basis in each case, was slightly modified. Theoretically, the number of classifications was increased, but actually it was fewer, as the cotton handkerchiefs were imported in the main under the minimum clause.

Under the act of 1913 cotton handkerchiefs unhemmed were dutiable at 25 per cent ad valorem; if hemmed or hemstitched, 30 per cent ad valorem.

The emergency tariff act of May 27, 1921, provided a compensatory duty of 7 cents per pound on all manufactures of cotton having a staple of $1\frac{3}{8}$ inches or over. This provision applied to a large proportion of the cotton handkerchiefs imported.

In the act of 1922, paragraph 918, unhemmed cotton handkerchiefs are dutiable as the cloth of which made, whereas those hemmed or hemstitched pay 10 per cent ad valorem in addition thereto. A minimum ad valorem rate of 30 per cent is provided for those containing yarns the average number of which does not exceed 40, and a minimum rate of 40 per cent on those made of finer yarns.

COMPETITIVE CONDITIONS.

Under the acts of 1897 and 1909 imports of plain cotton handkerchiefs were so small as to show that the minimum rates of 45 per cent on unhemmed or hemmed handkerchiefs and of 55 per cent on hemstitched handkerchiefs were practically prohibitive. Considerably over nine-tenths of the imports under those acts were entered under the minimum rate provisions, indicating that the small imports were of finer and higher-priced grades than those made in this country.

Imports under the act of 1913, with rates of 25 and 30 per cent, increased, but with the exception of the abnormal purchases during

the fiscal year 1920, when the demand for all kinds of goods appeared insatiable, were less than a half million dollars a year, and even the record imports of 1920, amounting to something over a million dollars, constituted less than 5 per cent of the domestic production.

Medium grade cloths, such as staple print cloths, are made in the United States in enormous quantities and, aided by the automatic loom, which is as yet little used abroad, at prices that do not permit of foreign competition either on the cloth or on articles, such as handkerchiefs, which are but a stage removed therefrom. The competitive status of foreign cotton cloths and of handkerchiefs made therefrom improves with any increase in the fineness, in other words, with any increase in the ratio of labor cost to the total cost.

TARIFF CONSIDERATIONS.

Cotton cloth when bleached, as most handkerchief cloth is, was dutiable under paragraph 252 of the act of 1913 at 10 to 30 per cent ad valorem, according to the fineness of the yarn from which woven. A flat duty on the advanced article—25 per cent if not hemmed and 30 per cent if hemmed or hemstitched—bore unevenly, therefore, upon handkerchiefs made of different grades of cloth, imposing a much higher duty on the lower grade handkerchiefs, as compared with the cloth of which composed, than on the finer grades, which paid a slightly higher duty, or the same rate as the component cloth. Thus, handkerchiefs made of yarns under 40s paid the duty of 25 or 30 per cent, while the cloth of which they were composed was subject to only 15 per cent; handkerchiefs made of yarns finer than 80s, at the other extreme, were subject to practically the same rate of duty as the cloth of the same fineness (27½ to 30 per cent). Hence it was possible for cotton cloth made of fine yarns over 80s to be cut into handkerchiefs, but not hemmed, and imported under this paragraph at a lower rate of duty than if imported as cloth in the piece.

As the rates on cotton handkerchiefs were ad valorem, they automatically provided for increased duty on each additional process of manufacture which advanced the value of the commodity. This, of course, was nullified in the case of unhemmed handkerchiefs made of cloth dutiable at more than 25 per cent, but on the other hand, amounted to a double differential on lower grades of cotton handkerchiefs.

STATISTICAL TABLES.

Cotton handkerchiefs or mufflers [1]—Imports by countries, 1912–1922.

[Fiscal years.]

Imported from—	1912	1913	1914	1915	1916	1917

Cotton handkerchiefs and mufflers, hemmed or hemstitched—Rates of duty.

Act of—	Par.	Tariff classification or description.	Rate of duty.
1883	325	Cotton * * * hemmed handkerchiefs, * * *	40 per cent ad valorem.
1890	349	* * * handkerchiefs, * * * composed of cotton or other vegetable fiber, or of which cotton or other vegetable fiber is the component material of chief value, made up or manufactured wholly or in part by the tailor, seamstress, or manufacturer, * * * not specially provided for in this act.	50 per cent ad valorem.
	373	* * * hem-stitched handkerchiefs composed of flax, jute, cotton or other vegetable fiber, or of which these substances or either of them, or a mixture of any of them is the component material of chief value, not specially provided for in this act.	60 per cent ad valorem.
1894	258	* * * handkerchiefs, * * * composed of cotton or other vegetable fiber, or of which cotton or other vegetable fiber is the component material of chief value, made up or manufactured wholly or in part by the tailor, seamstress, or manufacturer, * * * not specially provided for in this Act.	40 per cent ad valorem.
1897	312	Handkerchiefs or mufflers [1] composed of cotton, whether in the piece or otherwise and whether finished or unfinished, if not hemmed, or hemmed only, shall pay the same rate of duty on the cloth contained therein as is imposed on cotton cloth of the same description, weight, and count of threads to the square inch; but such handkerchiefs or mufflers shall not pay a less rate of duty than	45 per cent ad valorem
		If such handkerchiefs or mufflers are hemstiched, or imitation hemstitched, or revered, or have drawn threads, they shall pay a duty of ten per centum ad valorem in addition to the duty hereinbefore prescribed, and in no case less than	55 per cent ad valorem.

[1] As cloth, see pars. 304–310, inclusive.

Cotton handkerchiefs and mufflers, hemmed or hemstitched—Rates of duty—Continued.

Act of—	Par.	Tariff classification and description.	Rate of duty.
1909....	322	Handkerchiefs or mufflers[2] composed of cotton, whether in the piece or otherwise and whether finished or unfinished, if not hemmed, or hemmed only, shall pay the same rate of duty on the cloth contained therein as is imposed on cotton cloth of the same description, weight, and count of threads to the square inch: but such handkerchiefs or mufflers shall not pay a less rate of duty than	45 per cent ad valorem.
		If such handkerchiefs or mufflers are hemstitched, or imitation hemstitched, or revered, or have drawn threads, they shall pay a duty of ten per centum ad valorem in addition to the duty hereinbefore prescribed, and in no case less than	55 per cent ad valorem.
1913....	255	Handkerchiefs or mufflers composed of cotton, not specially provided for, in this section, whether finished or unfinished, not hemmed.	25 per cent ad valorem.
		hemmed, or hemstitched.[3]	30 per cent ad valorem.
1922....	918	Handkerchiefs and mufflers,[2] composed wholly or in chief value of cotton, finished or unfinished, not hemmed, shall pay duty as cloth; hemmed or hemstitched, shall pay, in addition thereto, 10 per centum ad valorem: *Provided*, That none of the foregoing, when containing yarns the average number of which does not exceed number 40, shall pay less than 30 per centum ad valorem; nor when exceeding number 40, less than 40 per centum ad valorem.	

[2] As cloth, see pars. 315–320, inclusive.
[3] As cloth, see pars. 903 and 906.

Court and Treasury Decisions.

Handkerchiefs cut apart but not hemmed were classified as manufactures of cotton and not as handkerchiefs hemmed nor as cotton cloth nor cotton strips for frilling, under the act of 1883. Their not being hemmed was declared not to affect the fact that they were handkerchiefs. (T. D. 8606, of 1888.)

In a case under the act of 1890, unbleached textile fabric of Egyptian cotton in imitation of pongee silk, having handkerchief designs printed thereon and dotted lines between the designs to be followed in separating the handkerchiefs, and commercially known as cotton handkerchiefs in the piece, was held dutiable under paragraph 349 as handkerchiefs made up wholly or in part, and not as cotton cloth not bleached. The mere separation of the handkerchiefs was adjudged not a material process in the manufacture of the handkerchiefs. Squares of printed calico of plain cotton cloth, the size of handkerchiefs, cut from a piece, the Board of General Appraisers said, would not be removed from classification as countable cotton cloth. Cotton cloth itself must have undergone a process of manufacture whereby it was converted into some other article or articles more specifically enumerated in the tariff. The merchandise in issue was differentiated from printed cotton cloth by having been subjected to an additional process of manufacture and become popularly and commercially known as cotton handkerchiefs in the piece and suitable only for use as handkerchiefs. (G. A. 1995; T. D. 13801, of 1893.)

The term "handkerchiefs * * * unfinished" in paragraph 312 of the act of 1897 was interpreted to include cloth cut into squares and other geometrical figures and in that shape principally used in the manufacture of handkerchiefs. (Meyer *v.* United States, 138 Fed. 974.)

Paragraph 358 of the act of 1913 takes from the other handkerchief paragraphs all embroidered or scalloped handkerchiefs. (Field *v.* United States, 7 Ct. Cust. Appls. 30, of 1916.)

Muffler, as commonly understood, refers to something worn around the neck or throat, and, perhaps, mainly for warmth. (Vantine *v.* United States, 4 Ct. Cust. Appls. 3, of 1913.)

Plain drawnwork handkerchiefs were held dutiable under paragraph 322 of the act of 1909, and ornamental drawnwork handkerchiefs under paragraph 349 of the same act. (Abstract 36830; T. D. 34889, of 1914.)

Hemstitched handkerchiefs ornamented with drawnwork are more specifically provided for as "handkerchiefs * * * hemmed or hemstitched," at 30 per cent under this paragraph than as "articles from which threads have been omitted, drawn, punched, or cut, and with threads introduced after weaving, forming figures or designs, not including straight hemstitching," at 60 per cent under paragraph 358. (G. A. 7769; T. D. 35675, of 1915.)

READY-MADE CLOTHING AND ARTICLES OF WEARING APPAREL, N. S. P. F.

SUMMARY.

Paragraph 256 of the 1913 act included ready-made clothing and all articles of wearing apparel not specially provided for, of cotton or other vegetable fiber, with or without india-rubber. The paragraph has been treated in three parts: (1) Ready-made clothing and articles n. s. p. f.; (2) shirt collars and cuffs; and (3) corsets, not ornamented.

Excluded from the provisions of this paragraph were wearing apparel wholly of flax, hemp, or ramie (paragraph 278), knit goods (paragraphs 259, 260, 261), various small wares enumerated in paragraph 262, and wearing apparel specially ornamented by lace or embroidery (paragraph 258).

There are no statistics as to the exact size of the industry, or the annual production of unornamented cotton wearing apparel, the industry being closely affiliated and interwoven with the silk and wool garment industry and cotton clothing ornamented by lace or embroidery.[1] It is evident from the census figures of 1914 that the total production equaled several hundred million dollars and had practically doubled since 1904. Census figures were from manufacturers only and did not include the production of custom shops. It is probable that a large part of the growth of manufacturing is due to the transfer of work from custom establishments to factories, the remainder being due to increase in consumption and export.

In 1914 exports of cotton wearing apparel amounted to $8,220,626; in 1920 to $23,489,507. Canada is usually the largest purchaser, but others of importance are Cuba, Central America, Mexico, Philippine Islands, United Kingdom, British South Africa, and Australia.

The domestic wearing apparel industry admits of only a limited amount of competition from abroad. This is largely because manufacturers are equipped with the most up-to-date machinery and resort to all available means of high-speed production, producing mainly in bulk, and keeping their products well in line with the prevailing modes of style and fashion. Many of them have established a definite market for their goods by advertising and selling under trade-marks which represent a standard of quality.

The apparent decrease under the act of 1913 was due to the exclusion of gloves which were formerly the most important import under cotton wearing apparel.[2]

---

[1] The 1914 census calls attention to this fact and gives many figures on the value of production of various articles which are included in totals for other articles.

[2] For a discussion of the cotton-glove industry, see Tariff Information Survey 1-6.

General Information.

DESCRIPTION.

This section treats of articles of clothing and wearing apparel of every description (not ornamented by lace or embroidery) of which cotton or other vegetable fiber and india-rubber is the component material of chief value, except collars and cuffs, cotton corsets, and knit goods.

DOMESTIC PRODUCTION.

The wearing-apparel industry is found in varying phases to some extent in almost all thickly populated sections of the country. The establishments range in size from the home, equipped for contract work, to the large plant of a company capitalized at half a million or more.

Materials.—A large portion of the domestic production of all grades of cotton cloth such as shirting material, nainsook, cotton flannels and other material adaptable for cotton wearing apparel and clothing is consumed in the industry. Other materials are thread, tape, and bandings, buttons, clasps, hooks, and other findings. All of these are produced in ample quantities by the domestic textile and allied industries.

Equipment.—Electric cutting machines, sewing machines, buttonhole and button sewing machines which play a large part in the production of factory-made wearing apparel are all of domestic manufacture.

Methods of production.—While there are many small establishments, the bulk of production is from plants using power-driven machinery, adapted in every possible way to saving labor. Many ready-to-wear garments, such as shirts, house dresses, woven-fabric underwear, aprons and certain types of children's clothing are so standardized that large scale production admitting division of labor is possible. The workers are usually highly skilled, performing only one operation to each garment. Sixty per cent are women, paid by the piece.

Organization.—Because of the nature of the product the size of the establishments varies. Quantity production tends to concentrate the industry in large factories; but the comparatively small amount of capital required for equipment and the ready market for clothing make it an attractive field for small manufacturers who, however, find it increasingly difficult to compete on standard lines. As a rule the largest producers manufacture completed articles, but many put garments out at contract for certain operations. The majority of contractors do the work at home with only the family or one or two helpers in the organization.

Geographical distribution.—The industry is situated largely around the thickly populated centers, though small establishments are well scattered over the country. The bulk of the production is from New York, Chicago, Philadelphia, and Baltimore.

Domestic production and consumption.—Figures on the production of this class of wearing apparel and ready-made clothing are not available, but statistics for certain industries which would fall under this classification indicate that the total domestic output would be valued at several hundred million dollars.

Men's shirts to the value of $205,327,133 were manufactured in 1919 and "articles from textile fabrics for personal wear," including shirts and articles made from all fibers amounted to $3,198,147,094 in 1919.

Cotton wearing apparel is shown separately in export statistics which may be regarded as an index to the size and growth of this industry. To some extent American-made cotton clothing is shipped to all parts of the globe; during the years given in the table of exports, consignments to Canada ranged from $1,500,000 to almost $4,000,000; those to Cuba climbed steadily upward from $309,742 in 1910 to $8,101,290 in 1920; the United Kingdom and France, more variable customers, were credited with $7,618,861 and $1,116,852, respectively, in 1915, a year of heavy buying for war needs; a large part of the remainder was absorbed by Mexico, Central American countries, Argentina, Brazil, and British colonial possessions.

Exports, which include all cotton clothing, ornamented or not ornamented, are comparable with general imports. The alignment in the following table shows that exports exceeded imports in pre-war years, although not in the same proportions as since 1914. The increase in imports in the last few years was due to the large shipments received from the Philippine Islands of clothing ornamented with lace or embroidery, which amounted to $5,091,865 in 1920 and to $5,032,591 in 1921.

Foreign trade of the United States in cotton wearing apparel (except knit goods), 1910–1921.

	Exports.	Imports.	Year.	Exports.	Imports.
Fiscal year:			Fiscal year:		
1910	$4,549,921	$3,857,374	1917	$11,613,851	$2,841,793
1911	5,538,303	3,986,072	1918	8,750,698	2,794,852
1912	7,119,580	3,636,550	1919	10,873,417	3,317,655
1913	6,211,724	4,289,777	1920	19,648,303	8,065,722
1914	5,999,887	2,915,219	Calendar year:		
1915	14,743,148	1,174,427	1920	22,266,758	10,794,912
1916	11,213,181	1,516,051	1921	7,144,179	7,961,128

FOREIGN PRODUCTION.

No statistics of foreign production are available, but England, Germany, France, and Japan are the countries where the production of cotton wearing apparel has become an important factory industry; this is especially true of men's shirts and underwear. Probably in no other country is women's ready-made clothing so widely used and manufactured as in the United States. However, the manufacture of women's shirtwaists is a special industry in Nottingham, England. Quantities of handmade blouses are made in France at exceedingly low costs.

IMPORTS.

Imports of cotton wearing apparel can not be compared over an extended series of years because of the changes in classification under the different tariff acts. All cotton gloves were imported as "wearing apparel" prior to the act of 1909, wherein special provision was made for men's and boys' cotton gloves but not for women's gloves, which were still included with wearing apparel. The act of 1913

made the clause relating to cotton gloves inclusive of those worn by women. Hence statistics of cotton wearing apparel imports since October 4, 1913, do not include gloves.

In former years practically all of the cotton gloves imported came from Chemnitz, Germany, so that an approximate average of the value imported can be obtained from the Daily Trade and Consular Reports, which show that the value of cotton gloves declared for export at the American consulate in the Chemnitz district (and a small amount at Berlin) averaged $1,759,167 annually from 1909 to 1913, inclusive. Total unornamented cotton wearing apparel imports for consumption during the same five years averaged $1,891,290, allowing only a small margin for imports of other plain cotton wearing apparel included in this classification. The exports given in consular reports are for calendar years, while the imports for consumption are for fiscal years, so that the five years considered in each case do not cover identical periods; the difference, therefore, between the above figures can be regarded as indicative only in a general way of the import values of plain cotton wearing apparel, but it seems evident that they were less than in succeeding years. During the first three months of 1914 imports, which were dutiable under the act of 1909 and which included women's gloves, amounted to $677,302, whereas the imports for the remaining nine months, with all gloves excluded, amounted to only $388,062, although the rate had been reduced from 50 to 30 per cent. The total imports for 1915 were valued at $311,282 and for the fiscal year 1920 at $620,123, which increase in value, considering the rise in prices, probably did not represent an increase in the volume of trade.

Imports for the calendar year 1920 were valued at $1,226,819. Undoubtedly a large proportion of this consists of handmade articles from France, especially blouses, which during 1920, 1921, and 1922 had a wide vogue. They have been seen in the shops in great quantities and retailed at extremely low prices, from $2 up.

Imports for consumption of wearing apparel composed in part of india-rubber, though separately stated until 1910, have been included with other wearing apparel in the table given in this survey, as the values were usually small, averaging, under the act of 1897, $3,113, which was much exceeded in 1909, when imports equaled $17,441.

Consideration of the statistics of imports by countries is further complicated by the inclusion of wearing apparel ornamented with lace or embroidery. A similar process of elimination as carried out above will give additional proof that imports of plain cotton wearing apparel were small during the period when no separate statistics were available. Imports by countries of cotton wearing apparel averaged $3,697,841 (1909–1913). If imports for consumption of ornamented cotton wearing apparel, averaging $1,815,397, and the declared exports of German gloves are deducted from the imports by countries, the remainder, representing plain wearing apparel will correspond roughly to the amount obtained by the use of the figures for imports for consumption. It has been impossible to ascertain the value of plain cotton wearing apparel received from each country, though an examination of imports by countries of all cotton wearing apparel, will give an idea of the principal sources. Germany contributed the greatest values from 1910 to 1913, the bulk of which is known to

have been cotton gloves. France was second during those years, and assumed first place from 1914 to 1917, since when her exports to the United States have been surpassed by those from the Philippine Islands. All but a small proportion of those from the Philippine Islands are ornamented with lace or embroidery. In former years, the United Kingdom held third place, although far exceeded by France and Germany, but since 1915 imports from Japan have been greater than those from the United Kingdom. Japanese trade statistics disclose the fact that kimonas form the bulk of the cotton wearing apparel sent to this country. Imports in increasing amounts have come from Switzerland, and before the war a small part of this trade was with Austria-Hungary.

TARIFF HISTORY.

Ready-made clothing and articles of wearing apparel composed of cotton or other vegetable fiber were provided for in the act of 1890 at 50 per cent ad valorem with the proviso that if partially of india-rubber they should pay 50 cents per pound in addition. The tariff of 1894 reduced the rate to 40 per cent and eliminated the proviso. In the act of 1897 a clause was inserted providing for rubber garments for outside wear with a duty of 15 cents per pound in addition to the 50 per cent ad valorem regularly assessed upon the articles in the paragraph. The act of 1909 omitted the proviso, but retained the duty of 50 per cent ad valorem on all wearing apparel composed of cotton or other vegetable fiber and not ornamented with lace or embroidery. The tariff of 1913 repeated the wording of the paragraph in the act of 1909 with the addition "of cotton or other vegetable fiber and india rubber," but without a special rate for such garments, covering all items in the paragraph by a flat rate of 30 per cent ad valorem.

In the act of 1922, paragraph 919, provision is made for "clothing and articles of every description, manufactured wholly or in part, composed wholly or in chief value of cotton, and not specially provided for" at a flat rate of 35 per centum ad valorem. The time-honored phrase "made up or manufactured, wholly or in part, by the tailor, seamstress, or manufacturer" was omitted as useless verbiage. Paragraph 919 is confined to wearing apparel wholly or in chief value of cotton, omitting the former phrase "or other vegetable fiber" with the intent that wearing apparel wholly or in chief value of vegetable fibers other than cotton shall fall under schedule 10. Mention of india-rubber as a component material has been omitted as unnecessary since the paragraph covers wearing apparel wholly or in chief value of cotton, irrespective of whether india-rubber or other material is also contained in the goods. The revised wording was made as concise and definite as possible.

COMPETITIVE CONDITIONS.

The larger part of the domestic production, both in quantity and value, is of staple articles on which domestic competition is very keen. Whereas no accurate comparison of production and imports has been possible because census classifications do not coincide with nor even

parallel those of the 1913 tariff act, it is evident that imports amounting to only $1,226,819 in 1920 do not equal 1 per cent of the domestic production—in fact, they are less than 1 per cent of the domestic production of men's shirts, which amounted to $205,327,133 in 1919. The sale of wearing apparel is largely governed by style, and the American public is not, as a rule, satisfied with foreign-made garments, except in the more expensive lines. In factory-made clothes the American product can probably hold the domestic market by reason of its superiority. The small quantities of wearing apparel, with the exception of gloves, which were imported under this paragraph, support this statement.

STATISTICAL TABLES.

Cotton wearing apparel other than knit goods [1]*—Imports by countries, 1910–1922.*

[Fiscal years.]

Imported from—	1910	1911	1912	1913	1914	1915

Rates of duty—Cotton wearing apparel—Ready-made clothing and articles n. s. p. f.

Act of—	Par.	Tariff classification or description.	Rate of duty.
1890....	349	Clothing ready made, and articles of wearing apparel of every description, * * * and neckties or neckwear, composed of cotton or other vegetable fiber, or of which cotton or other vegetable fiber is the component material of chief value, made up or manufactured wholly or in part by the tailor, seamstress, or manufacturer, all of the foregoing not specifically provided for in this act,	50 per cent ad valorem.
		Provided, That all such clothing ready made and articles of wearing apparel having India rubber as a component material (not including gloves or elastic articles that are specially provided for in this act) shall be subject to a duty of	50 cents per pound, and in addition thereto 50 per cent ad valorem.
1894....	258	Clothing ready made, and articles of wearing apparel of every description, * * * neckties or neckwear, composed of cotton or other vegetable fiber, or of which cotton or other vegetable fiber is the component material of chief value, made up or manufactured wholly or in part by the tailor, seamstress, or manufacturer, all of the foregoing not specially provided for in this Act.	40 per cent ad valorem.
1897....	314	Clothing, ready-made, and articles of wearing apparel of every description, including neck-ties or neckwear, composed of cotton or other vegetable fiber, or of which cotton or other vegetable fiber is the component material of chief value, made up or manufactured, wholly or in part, by the tailor, seamstress, or manufacturer, and not otherwise provided for in this Act,	50 per cent ad valorem.
		Provided, That any outside garment provided for in this paragraph having india-rubber as a component material shall pay a duty of	15 cents per pound and 50 per cent ad valorem.
1909....	324	Clothing, ready-made, and articles of wearing apparel of every description, composed of cotton or other vegetable fiber, or of which cotton or other vegetable fiber is the component material of chief value, made up or manufactured, wholly or in part, by the tailor, seamstress, or manufacturer, and not otherwise provided for in this section.	50 per cent ad valorem.
1913....	256	Clothing, ready-made, and articles of wearing apparel of every description, composed of cotton or other vegetable fiber, or of which cotton or other vegetable fiber is the component material of chief value, or of cotton or other vegetable fiber and india rubber, made up or manufactured, wholly or in part, by the tailor, seamstress, or manufacturer, and not otherwise specially provided for in this section.	30 per cent ad valorem.
1922....	919	Clothing and articles of wearing apparel of every description, manufactured wholly or in part, composed wholly or in chief value of cotton, and not specially provided for.	35 per cent advalorem.

Court and Treasury Decisions.

Cotton wearing apparel upon which was sewn strips or bands of goods figured in different colors for ornamental purposes only were held not to be "appliquéd" and to be dutiable as cotton wearing apparel only. (United States *v.* Hamburger Levine Co., 5 Ct. Cust. Appls. 217.)

Tucked shirt bosoms of cotton or flax not embroidered or appliquéd, tuckings chief value, were held dutiable under this paragraph as wearing apparel composed in chief value of cotton rather than as articles made in whole or in part of tuckings under paragraph 358. (United States *v.* Snow's U. S. Sample Exp. Co., 6 Ct. Cust. Appls. 120, of 1915.) This decision was followed in classifying untrimmed hats made of cotton braid and thread (Abstract 38935, of 1915) and hat forms or shapes composed in chief value of cotton netting (Abstract 38719, of 1915) under this paragraph as cotton wearing apparel. This paragraph was also held more specific than articles made from pile fabrics (par. 257) for bibs made of cotton terry cloth (Abstract 38388, of 1915). Slippers made of cotton and leather, the parts of the slippers composed of each of the two materials being made separately for use in producing the completed article, cotton in chief value, were held dutiable under paragraph 324 of the act of 1909. In determining the component of chief value in merchandise of this kind, inquiry will be made to discover at what stage the several component parts were united to form the completed whole; that stage will be "its condition as found in the article." Here the expense of sewing the pieces of cotton cloth together in preparation for uniting them with the leather parts entered into the value of the cotton so employed. (United States *v.* Meadows, 2 Ct. Cust. Appls. 143, of 1911.) In the case of Chinese shoes, leather was the greatest in value of any single component, but cotton and ramie together constituted the component in chief value. They were also held dutiable as wearing apparel within this paragraph on the ground that the phrase "composed of cotton or other vegetable fiber, or of which cotton or other vegetable fiber is the component material of chief value" should be interpreted as if the conjunction "or" were "and." (Abstract 43034, of 1919.) Insoles for shoes in chief value of cotton (Abstract 43219, of 1919) and insoles for shoes made from the manufactured pith of a gourd, not woven, but cut into the shape of the human foot and pressed (Abstract 43039, of 1919) were also classified under this paragraph.

Waterproof garments made by cementing with rubber a cotton cloth to a cotton and wool cloth, or cotton and silk cloth to cotton and wool cloth, the rubber in each case being negligible in value, are composed in chief value of cotton, wool, or silk, according to which represents the greatest value as yarns plus its proportion on the basis of quantity, of the cost of weaving, and other expenses incurred in making the cloth and bringing it to the condition it had immediately prior to its combination with the other materials in order to form the goods in question. For this purpose cloth composed in chief value of one of these fibers should not be regarded as made entirely of it. (True Fit Waterproof Co. *v.* United States, 7 Ct. Cust. Appls. 489, of 1917.) (In some cases it has been found impracticable to distribute charges upon a quantity basis; in such cases the basis is value.)

Shoes made of leather and cotton and another vegetable fiber, the leather being more valuable than either of the other materials but less valuable than both, were held not to come within the provision in paragraph 256 of the act of 1913 for "wearing apparel * * * of which cotton or other vegetable fiber is the component material of chief value," but within the provision in paragraph 530 exempting from duty "shoes * * * in chief value of leather." (Chin *v.* United States, 11 Ct. Cust. Appls., — of 1921; T. D. 38932.)

SHIRT COLLARS AND CUFFS.

General Information.

DESCRIPTION.

Shirt collars and cuffs, as specifically mentioned in this paragraph of the 1913 act, refer to detached collars and cuffs made entirely of cotton, whether for men, women, or children. Men's collars are manufactured in a wide variety of size and shape and can in the main be divided into two classes, namely, the soft or unstarched, and the stiff or starched. Soft or unstarched collars have only recently come into general use and are made in the form of a soft folded collar and military stock; stiff collars are usually either folded, standing, or wing collars. Detached cuffs, now very little used, need not be considered separately, as the materials employed and processes of manufacture are identical with those of starched collars. As a substitute, collars and cuffs are sometimes made from paper or celluloid, but the use is not sufficiently general for them to be considered as competing articles. When the industry first started, linen was the chief material, but cotton collars, starched and unstarched, most of which are for men, now constitute the great bulk of the trade.

DOMESTIC PRODUCTION.

The manufacture of detached collars and cuffs originated in this country in 1825, and the United States has from the beginning of the industry been the largest producer and consumer.

Materials.—A number of different cotton cloths are used in the manufacture of collars and cuffs. In the stiff or starched article the cloths used are rarely other than plain-woven fabrics which are woven in the gray and afterwards bleached. Those used in the interlinings, which give body to the collar and serve as a holder for the starch, are coarse heavy sheetings. The inner surface of the collar, the portion which comes in contact with the neck of the wearer, is composed of medium weight cloths, usually printcloths, whereas the exposed outer surface of the collar is composed of somewhat finer cloths such as longcloths or nainsooks.

The following particulars, of typical cotton cloths in the gray largely used in the manufacture of stiff white collars, are supplied by leading manufacturers:

Width in inches.	Yards per pound.	Ends and picks per square inch.	Total threads per square inch.	Official average yarn count.
40	2.50	48 by 48	96	11.4
36	3.00	48 by 44	92	11.8
40	2.85	48 by 44	92	12.5
40	2.85	48 by 48	96	13.0
40	3.75	44 by 40	84	15.0
40	3.75	48 by 44	92	16.4
40	4.25	44 by 40	84	17.0
40	3.75	48 by 48	96	17.1

Width in inches.	Yards per pound.	Ends and picks per square inch.	Total threads per square inch.	Official average yarn count.
40	4.25	48 by 44	92	18.6
40	5.00	44 by 44	88	21.0
40	5.50	44 by 44	88	23.0
39	4.25	72 by 76	148	29.2
39	4.00	80 by 80	160	29.7
38½	5.35	64 by 60	124	30.4
39	4.75	68 by 72	140	30.9
39	3.90	80 by 92	172	31.1
39	3.85	96 by 112	208	37.2
39	3.95	96 by 108	204	37.4
39	4.15	96 by 100	196	37.8

In soft collars the general construction is the same except that the interlining is often made of two or three plies of a lighter cloth than that used in stiff collars. In the exposed outer surface a great variety of material is used, some of the most popular being English, French, and domestic piqués, corded madras, checks, and dobby figures, also various colored novelties, some of which contain silk or artificial silk. It is only in the novelty soft collars that any amount of imported material is used.

Equipment.—The cutting, sewing, and laundering machinery necessary in this industry is extensively manufactured in this country; practically none is required from abroad.

Methods of production.—There are six important stages in the manufacture of collars, namely, shrinking, cutting, turning, stitching, buttonholing, and laundering. While power-driven machines are used in all of the main operations and handwork is cut to a minimum, the essential factor is hand labor. Most of the workers in the actual manufacture are women, highly trained in the operation of their individual machines. Foreign methods of manufacture are largely the same, and the main difference, aside from wages, has been in the minimum age limit.[1]

Organization.—The industry is conducted on a highly efficient and well-organized basis. There are 39 establishments having a combined capitalization of $30,146,935. The major portion of the domestic production is by three companies of large physical proportions and ample capital. These companies have attained their present growth by the absorption of weaker competitors and by actual increase in volume of business. In most cases the larger concerns do their own jobbing, and thereby save a portion of the jobbers' profit.

Putting work out at contract is a common practice, especially among the small establishments.

Geographical distribution.—The industry is almost entirely centered around Troy, N. Y., which in 1914 produced 90 per cent of the entire domestic production. In 1914 there were 35 factories in the United States of which 24 were in New York State, 4 in Pennsylvania, and 7 in other States.

Value of output.—Domestic production in 1919 was valued at $47,564,949.

Domestic exports.—Previous to 1918 the figures on collars and cuffs were not given separately, but in that year they amounted to $321,346,

[1] The foreign worker often starts at 14 or under, and in some countries works an apprenticeship without pay.

the greater part of which went to Canada, Mexico, the Philippine Islands, and Cuba.

Domestic exports increased to a value of $954,374 in the fiscal year 1920. In 1921 the export of collars decreased to $341,789, in line with the marked diminution of exports in most other lines. Leading manufacturers have established branch houses in foreign countries. For the year 1913–14 two concerns reported export business amounting in total to $198,688,[2] most of which went to Great Britain and the English-speaking nations of the world, and to the West Indies, Mexico, Central and South America. This export trade has been due to quality, style, and trade-mark, rather than to price.[3]

FOREIGN PRODUCTION.

The main foreign producers of collars are Germany, England, France, and Japan, but the output of these countries has never reached the volume of domestic production nor have imported collars come into such general popular use.

IMPORTS.

Imports of collars and cuffs, always negligible, are, according to a study published by the Department of Commerce,[6] largely the kinds worn by women and children. In 1910 the importation amounted to 2,508 dozens, valued at $2,430; in 1914 imports were 5,368 dozens, with a value of $5,619; while in 1918 they were 23,808 dozens, valued at $36,252, from which the revenue was $10,876.

The largest volume of imports in any year to and including 1921, was 37,833 dozens, valued at $75,228 in 1920. Imports for 1921 were 25,167 dozens, valued at $49,075. A large proportion of the collars and cuffs imported is made of fabric containing cotton 1⅜ inches and over in length. Under the emergency tariff act of May 27, 1921, these were subject to an additional compensatory duty of 7 cents per pound.

TARIFF HISTORY.

Collars and cuffs of cotton were first specifically mentioned in the act of 1890 with a rate of 15 cents per dozen and 35 per cent ad valorem. Although not designated in the act of 1894 more specifically than as "ready-made clothing" and "neckwear," at 40 per cent ad valorem, the Department of Commerce retained the statistical classification "collars and cuffs, entirely of cotton," so that the figures which appear in the table of imports for consumption for the years under the act of 1894 are directly comparable with those of preceding years. The word "shirt" qualifying collars and cuffs first appeared in the act of 1897 and has been retained in subsequent acts. The provisions under the acts of 1897 and 1909 were identical, assessing a compound rate of 45 cents per dozen pieces and 15 per cent ad valorem. In 1913 this was equivalent to an ad valorem duty of 59.59 per cent and a specific duty of 60.1 cents per dozen pieces. The tariff rate of the act of 1913 was 30 per cent, which in 1920 was equivalent to a specific rate of 56.3 cents per dozen pieces. The rate under the act of 1922 is 30 cents per dozen pieces and 10 per centum ad valorem.

[2] See Department of Commerce report, Miscellaneous Series No. 36, "The shirt and collar industries."
[3] See tariff hearings before Committee on Ways and Means, 1913, pp. 3822, ff.

COMPETITIVE CONDITIONS.

Imports increased under the lowered rate of duty but that they were not competitive with the domestic product was evinced by the fact that in 1920 they amounted to less than two-tenths of 1 per cent of the total output of 1919. Moreover, exports for 1920 were 23 times as great as imports and had increased threefold from 1918 to 1920.

The lack of competition was due largely to the fact that the domestic industry has been long established and large enough to take care of all requirements and to the further fact that American makes are regarded as superior and as more up to date than any yet evolved by foreign producers.

STATISTICAL TABLES.

Cotton wearing apparel—Shirt collars and cuffs[1]*—Imports for consumption—Revenue, 1891–1921.*

CORSETS, NOT ORNAMENTED.

General Information.

DESCRIPTION.

The corset was not specially mentioned in paragraph 256 of the act of 1913, but was included by virtue of being wearing apparel. It is an inner article of dress, usually stiffened by strips of steel or whalebone, to support the body or modify its shape. Paragraph 256 covered only plain cotton corsets, those ornamented by lace or embroidery being included in paragraph 358, Schedule N.

DOMESTIC PRODUCTION.

This is one of the largest and most important individual branches of the domestic clothing and wearing-apparel industry. In 1919 there was approximately $43,516,486[1] invested capital, but as nearly every company produces all grades of corsets it is impossible to say just what portion of this capital was concerned with the manufacture of the plain cotton variety. In fact, almost all corsets have at least a finish of narrow lace.

Materials.—The main material used is coutil, often called corset cloth. It is strong, heavy, closely woven cloth made of medium coarse yarns. The weave is usually a five-harness warp sateen. Other materials used are wool cloth, elastic fabric, thread, metal clasps or hooks, together with flexible steel called ribs or bones, and laces. The bulk of these materials is of domestic manufacture. Formerly strips of whalebone, because of their strength and spring, were employed to give stiffness to corsets, but the scarcity and high price of this material has almost precluded its use.

Equipment.—Power-sewing machines play a large part in the manufacture of corsets. These, as well as machines for various special operations, are of domestic manufacture.

Methods of production.—There is no general standardization in the industry; each manufacturer makes special styles, and even these change from season to season, according to the trend of fashion. The manufacture necessitates considerable hand work in conjunction with the sewing machine, but special machinery is employed whenever possible. About 83 per cent of the workers are women.

Geographical distribution.—The State of greatest production is Connecticut, the industry centering around Bridgeport; other producing States are New York, Michigan, New Jersey, Massachusetts, and Illinois.

---

[1] Federal Census, 1919

Organization.—The industry is conducted on a highly efficient and well-organized scale, the major portion of the production coming from establishments capitalized at $100,000 to $1,000,000. In 1919 there were in all 188 concerns employing a total of 18,415 wage-earners.

Domestic production and consumption.—Exact figures on the production of plain cotton corsets as distinct from ornamented, are not available, but the entire value in 1914 was $40,551,000,[2] and in 1919 $475,541,959, the major portion of which was for domestic consumption.

EXPORTS.

Domestic exports, though fluctuating, are large. In 1914 exports were valued at $2,226,739; in 1918 at $1,819,767; in 1920 at $3,583,767; and in 1921 at $1,695,555. These figures represent the total domestic exports of all kinds. The best markets for American-made corsets are now found in the United Kingdom, Australasia, Canada, and British South Africa.

IMPORTS.

Imports of plain cotton corsets are practically negligible. In 1910, imports amounted to 2,390 dozen pairs, valued at $47,653; in 1914, 150 dozen pairs, valued at $1,273; and in 1921, 1,144 dozen pairs, valued at $7,599. The revenue derived therefrom in the last year was $2,280. Even combining the imports of plain and ornamented corsets the totals are small, in comparison with domestic production, amounting to a value of $54,047 in 1910, to $43,486 in 1914, and to $23,386 in 1921.

TARIFF HISTORY.

Corsets have never been specifically mentioned in the tariff acts since 1883, when all grades of the article were classed under one paragraph at 35 per cent ad valorem. Under the acts of 1890, 1894, 1909, 1913, and 1922 they were classed, when not ornamented, under articles of wearing apparel not specifically mentioned, with respective rates of 50 per cent, 40 per cent, 50 per cent, 30 per cent, and 35 per cent ad valorem.

COMPETITIVE CONDITIONS.

The domestic industry, while in a highly competitive state as a whole, hardly admits of any competition from abroad. It has been long established and takes care of all domestic needs with articles of the latest accepted style and of better workmanship than are produced elsewhere. The reduction of the tariff from 50 per cent to 30 per cent in 1913 had no effect on imports; in fact the imports in 1914 were less than in 1913.

PREFACE.

This is one of a series of tariff information surveys prepared by the United States Tariff Commission and transmitted to the Committee on Ways and Means. The series covers all of the articles and commodities provided for in the tariff act of October 3, 1913, and others not specifically provided for. It is arranged in the numerical order of paragraphs of that act.

In some cases two or more paragraphs have been combined in one pamphlet. In doing this, industrial relationship of the articles has been followed when possible. In those instances where a paragraph has been treated under a preceding paragraph of the tariff act, reference is made to this fact at the point where the paragraph appears in numerical order. Where one grade of an article is dutiable and another grade of the same article is on the free list, the article is discussed under the dutiable paragraph which appears first in numerical order in the tariff act. In certain instances articles of close industrial relationship and which occur in separate paragraphs of the tariff act have been combined under one paragraph for convenience of discussion. Reference is made to this fact at the point where the commodities would naturally occur in numerical order.

The first pamphlet in the series is an "Introduction and index," which contains—

1. An introductory chapter discussing the scope of the series and the general method of treatment.
2. An alphabetical index of the articles provided for in the tariff act of 1913, showing the paragraph of the act in which the article is provided for and, if discussed under a different paragraph, the number of such paragraph.
3. A list of the pamphlets in the series, showing the paragraphs and articles included in each pamphlet.

Thus by use of this "Introduction and index" the exact location of the discussion relating to a given article or commodity can be ascertained.

In the preparation of this report the Tariff Commission had the services of W. A. Graham Clark, special expert, and of others.

COTTON CLOTHS PROVIDED FOR EO NOMINE.

TARIFF ACT OF OCTOBER 3, 1913.

Text of Schedule I relating to cotton cloths provided for eo nomine:

PAR. 254. Cloth composed of cotton or other vegetable fiber and silk, whether known as silk-striped sleeve linings, silk stripes, or otherwise, of which cotton or other vegetable fiber is the component material of chief value, and tracing cloth, 30 per centum ad valorem; cotton cloth filled or coated, all oilcloths (except silk oilcloths and oilcloths for floors), and cotton window hollands, 25 per centum ad valorem; waterproof cloth composed of cotton or other vegetable fiber, or of which cotton or other vegetable fiber is the component material of chief value or of cotton or other vegetable fiber and india rubber, 25 per centum ad valorem.

PAR. 257. Plushes, velvets, plush or velvet ribbons, velveteens, corduroys, and all pile fabrics, cut or uncut, whether or not the pile covers the entire surface; any of the foregoing composed wholly or in chief value of cotton or other vegetable fiber, except flax, hemp, or ramie; and manufactures or articles in any form, including such as are commonly known as bias dress facings or skirt bindings, made or cut from plushes, velvets, velveteens, corduroys, or other pile fabrics composed of cotton or other vegetable fiber, except flax, hemp, or ramie, 40 per centum ad valorem.

PAR. 258. * * * tapestries, and other Jacquard figured upholstery goods, composed wholly or in chief value of cotton or other vegetable fiber; any of the foregoing, in the piece or otherwise, 35 per centum ad valorem; * * *.

PAR. 263. Cotton table damask, and manufactures of cotton table damask, or of which cotton table damask is the component material of chief value, not specially provided for in this section, 25 per centum ad valorem.

SUMMARY.

Cotton cloths in general were provided for in paragraph 252 of the act of 1913. On these "countable cotton cloths" there were levied progressive rates of duty based on the average yarn count as officially calculated from the construction (ends per square inch) and the weight. Certain cotton cloths were excepted from these progressive rates and were provided for eo nomine at flat rates of duty, assessed without regard to yarn count, construction, or weight.

The relative importance of the various eo nomine cloths, as compared with countable cotton cloths, can be best illustrated by showing the average annual imports for consumption during the last two tariff acts.

Total cotton cloths	(1)	225,968,847	53,002,477	(1)	23.46	(1)

[1] No data.

Table 1 shows that of $48,624,228 worth of cotton cloths imported under the act of 1909, $34,155,180, or 70.24 per cent, consisted of countable cotton cloths, dutiable at progressive rates of duty, and $14,469,048, or 29.76 per cent, of cotton cloths provided for eo nomine, at flat (fixed) rates of duty. Table 1a shows that of $225,968,847 worth of cotton cloths imported under the act of 1913, $188,371,187, or 83.36 per cent, consisted of countable cotton cloths, and $37,597,660, or 16.64 per cent, of cotton cloths provided for eo nomine. Corresponding proportions according to quantities are not available because some of the eo nomine cloths were recorded only by value.

The question arises as to why certain cloths are singled out for special tariff treatment. The flat rates of duty levied on these eo nomine cloths are, in practically every instance, higher than the aver-

age rate of duty levied on cotton cloths in general, which would indicate that special rates were deemed desirable, because of higher labor cost percentages or for other reasons, but the exemption of these cloths from progressive rates of duty is doubtless due in most instances to the difficulty of ascertaining exactly the number of threads per square inch or the average yarn count. This would apply to cotton pile fabrics, to tapestries and other double-texture cloths, and to most filled or coated cloths, where the fabric would have to be disintegrated or the finish removed to ascertain the physical details for classification under progressive rates of duty. In the case of cotton-and-silk cloths it was probably due to the higher value and different yarn numbering system of silk as compared with cotton. (In the act of 1922, however, cotton-and-silk cloths have been made dutiable as countable cotton cloths, with an additional duty of 5 per cent ad valorem.) In the case of cotton table damask no reason is apparent for differentiation from other countable cotton cloths. These goods are composed of coarse to medium yarns, and the labor cost percentage is less than that of many other Jacquard fabrics of finer yarn counts which are dutiable at the regular progressive rates of duty.

In almost every American tariff some cotton cloths have been provided for by name at rates of duty higher than those applying to cotton cloths in general. In the tariff of 1790, for instance, there was a provision for a special rate of 7½ per cent ad valorem on "cambrics, muslins, muslinets, laces, gauzes, chintzes, and colored calicoes and nankeens," [1] whereas cotton cloths in general fell under the 5 per cent ad valorem levied on "all other goods." It may be noted also that in the tariff of 1864 there was a special duty, higher than that applicable to other cotton cloths, levied on "cotton jeans, denims, drillings, bedticking, ginghams, plaids, cottonades, pantaloon stuffs, and goods of like description," and that special treatment of such cloths was not abolished until 1883.[2] Cotton duck was provided for by name in the acts of 1894 and 1897; this eo nomine provision was dropped in 1909.[3]

Of the cotton cloths provided for eo nomine in the tariff act of 1913, it may be noted that cotton pile fabrics were the first to secure separate enumeration. The acts of 1790 and 1797 provided for "velvets and velverets," the first probably relating to silk velvets and the latter to cotton velvets or velveteens. In the acts from 1846 to 1883, inclusive, there was provision for "cotton velvet," but it was not until 1890 that the provision was expanded to the basis of the present wording in order to cover all cotton pile fabrics. Cotton damask was first mentioned in 1883 and cotton table damask in 1897. The first provision for cotton cloth containing an admix-

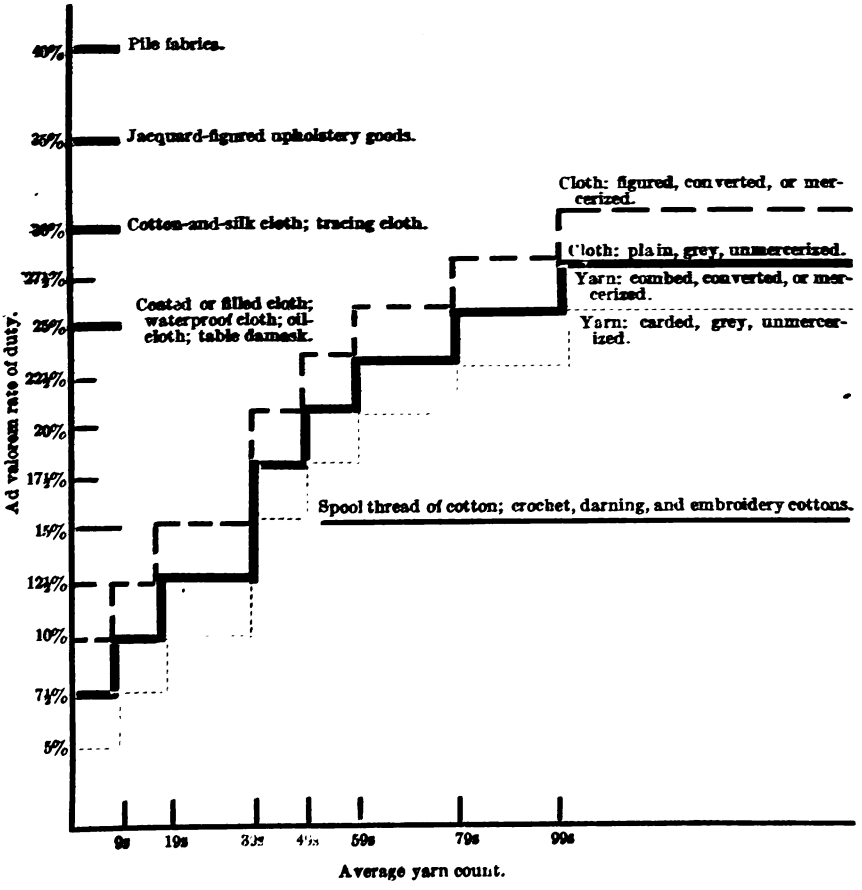
[1] These nankeens were the coarse narrow cotton cloths woven on hand looms in China. Nankeens are referred to in several of the earlier American tariffs, and imports and reexports were recorded separately for the fiscal years 1821–1842, inclusive. During these 22 years imports of nankeens were valued at a total of $4,469,198, ranging from a high of $823,365 in 1822 to a low of $53 in 1842. Reexports of nankeens were for the same 22 years valued at a total of $5,672,720. This higher value probably includes intermediate charges, but would tend to show that imports of nankeens were for reexport only. These reexports were widely distributed, going particularly to Mexico, Chile, Danish West Indies, Gibraltar, the Hanse Towns and German ports, Trieste and other Adriatic ports.

[2] During the 19 years, 1865–1883, inclusive, imports of the above-mentioned cloths, which were mainly coarse yarn-dyed fabrics, were recorded separately and averaged annually 4,404,636 square yards, valued at $826,891.

[3] The rates of duty on cotton duck in the acts of 1894 and 1897 were higher than on other countable cotton cloths, although duck is the heaviest and coarsest yarn fabric made of cotton and the one for which in the cost of production material constitutes the largest item and labor the smallest.

ture of silk was in the act of 1890. Waterproof cloth was provided for as early as 1883, but the act of 1897 was the first to mention the material, in "waterproof cloth, composed of cotton or other vegetable fiber." "Cotton cloth, filled or coated" was also listed for the first time in 1897. Oilcloths were mentioned in several of the earlier tariffs, but the phrasing "all oilcloths (except silk oilcloths and oilcloths for floors)" dates from 1909, as does the first mention of cotton window hollands and of tracing cloth. The act of 1909 was also the first in which there was a provision for "tapestries and other Jacquard figured upholstery goods," although with the modifying clause "weighing over 6 ounces per square yard"; the omission in the act of 1913 of this modifying clause caused considerable litigation and confusion.

CHART.—*Comparison of progressive rates of duty on cotton yarns (par. 250) and countable cotton cloths (par. 252) with the flat rates of duty on spool thread of cotton and crochet, darning, and embroidery cottons (par. 251), and the various cotton cloths provided for eo nomine (pars. 254, 257, 258, and 263), under the act of 1913.*



CLASSIFICATION.

Cotton cloths that were exempted from the progressive rates of duty levied on countable cotton cloths in general, in paragraph 252 of the act of 1913, were provided for eo nomine at flat rates of duty under paragraphs 254, 257, 258, and 263. Under the act of 1922 countable cotton cloths are dutiable under the provisions of paragraphs 903, 906, and 908, and eo nomine cloths are dutiable under paragraphs 905, 907, 909, 910, and 911.

CLOTHS OF COTTON (OR OTHER VEGETABLE FIBER) AND SILK.

[Paragraph 254, act of 1913; paragraph 908, act of 1922.]

SUMMARY.

The use of silk in the domestic cotton industry has greatly increased during the last decade, so much so that the production of cotton cloths ornamented with silk has become a prominent feature of the trade.

The import trade in cotton cloths containing silk is negligible as compared with the huge and increasing domestic output of such fabrics. Imports as recorded during the 30 fiscal years 1891–1920 averaged only $43,397 a year, with a record import of only $113,225 in 1915. For the calendar year 1921 the imports were 297,311 square yards valued at $79,882.

Exports of cotton cloths containing silk are not recorded separately but are considered to be fully as large as, if not larger than, the imports.

GENERAL INFORMATION.

DESCRIPTION.

Cloths of cotton and silk under paragraph 254 of the act of 1913 included any cloth exceeding 12 inches in width, regardless of weight or construction, which had cotton or other vegetable fiber as its component material of chief value and which included silk.

This provision was in practice confined almost entirely to cotton-and-silk cloths, as imports of silk-mixed fabrics in which a vegetable fiber other than cotton predominates in value are very rare.

DOMESTIC PRODUCTION.

Cotton-and-silk cloths have become increasingly popular during the last decade. The more staple varieties of cotton cloths containing an admixture of silk are silk-striped sleeve linings and various types of silk-striped shirtings. The greatest increase in production, however, has been in novelty dress goods, such as fancy voiles and ginghams.

Materials.—Domestic manufacturers in the majority of cases spin the cotton yarn used in the various grades of goods. The silk is usually purchased in the form of yarn, although a few of the cotton mills now have their own throwing plants and buy their silk in the raw state.

Equipment and methods of production.—Many fine-yarn cotton mills are equipped to weave silk-and-cotton cloths, as, with the exception of

the preparation of the yarn, the processes are the same. The machinery is mainly of domestic manufacture, and the only difficulty lies in training labor in the handling of silk.

Organization.—Very few mills have been organized for the exclusive manufacture of silk-and-cotton goods, although many cotton mills have taken it up as a novelty side line. These are mostly the larger and better-equipped mills previously turning out novelty cotton goods.

Geographical distribution.—While the major portion of the goods are made in the New England mills, several of the leading cotton mills of the South are now turning out some mixed-silk goods.

History of production.—There is no reason why domestic manufacturers could not have produced these goods long ago, lacking little but the knowledge of handling silk. Once started, however, the industry has progressed rapidly and there has been a phenomenal growth in production and in variety of patterns and uses. The first production was in novelty goods of very high grade. These were rapidly absorbed by the trade and at a good profit to the producer. As the demand increased and the goods became better known, converters, in order to meet competitive conditions, began to order a lighter construction of goods. These were produced at a correspondingly lower price and gave practically the same effect.

Domestic production and consumption.—Shirting and dress goods may be made much more elaborate by the introduction of silk threads without materially increasing the production cost. This fits in with the domestic production methods better than the making of novelties that require the use of more complicated and costly weaves. For this reason the domestic industry has been very successful and made rapid progress in the production of novelties containing silk. The value of the domestic production was not separately stated in the census reports until 1919, when shirtings (silk striped) were produced to the extent of 33,865,803 square yards, valued at $12,379,237, and cloths composed of cotton and silk or other vegetable fiber and silk (except silk-striped shirtings) were produced to the extent of 51,404,771 square yards, valued at $18,587,057.

Domestic mills have supplied the great bulk of the consumption and are largely responsible for the new designs which have materially increased the consumption of these fabrics.

DOMESTIC EXPORTS.

The export of cotton cloths containing silk is not recorded but is probably larger than the import. Even before the war the United States was exporting some silk-ornamented cotton cloths, including the shipment of dotted silk and cotton mulls to England itself, and with the expansion of the American export trade in cotton cloth in general there has been a considerable increase in the export of fancy fabrics, including many containing more or less silk.

IMPORTS.

Imports of cotton-and-silk cloths are so small that they have never been a factor in the domestic market; in recent years the tendency has been for imports to decline in quantity and to be confined almost entirely to the more staple lines.

Imports of cotton-and-silk cloths during the 30 fiscal years, 1891–1920, are shown in Table 2, which presents a complete statistical record of the importation of such goods since their first enumeration in the act of 1890. It is seen that imports of these goods have ranged from a low of 57,887 square yards, valued at $26,102, in 1894, to a high of 475,408 square yards, valued at $113,225, in 1915, with an average for the 30 years, 1891–1920, of only 149,583 square yards, valued at $43,397. During these 30 years the average value per square yard has ranged from 11.93 cents, in 1897, to 56.12 cents in 1920, with an average of 29.01 cents. For the calendar year 1921 the average value per square yard was 26.87 cents.

On an ad valorem basis the duty has ranged from 30 per cent, under the 1913 tariff, to 71.16 per cent in 1891, with a 30-year average of 50.34 per cent. For the calendar year 1921 the ad valorem rate averaged 31.35 per cent. On a specific basis the duty has ranged from 6.57 cents, in 1916, to 25.78 cents in 1894, with a 30-year average of 14.60 cents, per square yard. For the calendar year 1921 the equivalent specific duty was 8.42 cents per square yard.

TARIFF HISTORY.

Cotton cloth containing an admixture of silk was first provided for in the act of 1890 (par. 348), the duty being fixed at 10 cents per square yard and 35 per cent ad valorem. In the act of 1894 (par. 260), the duty was changed to a flat rate of 45 per cent ad valorem. In the act of 1897 (par. 311) this provision was widened to include cloths of cotton "or other vegetable fiber" containing an admixture of silk. The rate was fixed at 8 cents per square yard and 30 per cent ad valorem, with a minimum of 50 per cent. With the exception of the addition of a few words necessary to complete the sense of the 1897 provision, the wording of this provision in the act of 1909 (par. 321) was the same and there was no change in the rate of duty. In the act of 1913 (par. 254) there was no change in the wording, with the exception of the omission of the minimum proviso, but the rate was changed to a flat 30 per cent ad valorem.

In the act of 1922 (par. 908) the predominant material is restricted to cotton by the omission of the words "or other vegetable fiber," but the ornamenting material may be either silk or artificial silk, the latter being mentioned in this connection for the first time. The system of levying duties is also changed by reason of the removal of these fabrics from the eo nomine classification at a fixed rate of duty and their inclusion under the countable cotton-cloth classification at progressive rates of duty, based on the average yarn count, but with a surtax of 5 per cent ad valorem.

COMPETITIVE CONDITIONS.

The domestic industry is in a highly competitive state and, while there are no available figures to show exactly how many concerns produce goods directly under this class, it is known that there are many competing establishments who maintain designing departments and are continually producing new designs and effects. There is practically no competition from abroad.

STATISTICAL TABLES.

1909	321	Cloth, composed of cotton or other vegetable fiber and silk, whether known as silk-stripe sleeve lining, silk stripes, or otherwise, of which cotton or other vegetable fiber is the component material of chief value.	8 cents per square yard and 30 per cent ad valorem.
		Provided, That no such cloth shall pay a less rate of duty than.	50 per cent ad valorem.
1913	254	Cloth, composed of cotton or other vegetable fiber and silk, whether known as silk-striped sleeve linings, silk stripes, or otherwise, of which cotton or other vegetable fiber is the component material of chief value, * * *	30 per cent ad valorem.
1922	908	Cloth in chief value of cotton, containing silk or artificial silk, shall be classified for duty as cotton cloth under paragraphs 903, 904, and 906, and in addition thereto there shall be paid on all such cloth.	5 per cent ad valorem.
		Provided, That none of the foregoing shall pay a rate of duty of more than.	45 per cent ad valorem.

Court and Treasury Decisions.

Cotton cloth having figures of considerable size and attractive designs produced by the swivel process with extra threads of silk, assessed for duty as etamines, was held dutiable as cloth composed of cotton and silk under paragraph 311 of the act of 1897. The construction that fabrics not wholly or substantially of cotton were excluded from the countable clauses was invoked. (G. A. 6044, T. D. 26373 of 1905.) Under the act of 1909 cloth composed in chief value of cotton but in part of silk was held dutiable under paragraph 321 notwithstanding that the amount of silk in the fabric was insignificant. But the countable provisions were held to apply to cotton cloth having a selvage containing silk which was not designed to give character to the fabric or to form a material and essential part of the woven article when utilized by the consumer. (United States *v.* Mandel, 1 Ct. Cust. Appls., 223, of 1911.)

TRACING CLOTH.

[Paragraph 254, act of 1913; paragraph 907, act of 1922.]

Summary.

For a long time England, the first and largest producer of tracing cloth, supplied the bulk of the American demand, and English brands became firmly established through years of use.

After one fruitless attempt on the part of a domestic manufacturer to produce tracing cloth of a quality to compete with the English another took up this special line af manufacture in 1911; although this company progressed to a point where it supplied about half of the domestic demand it was unable to satisfy the requirements of the more exacting customers and closed down in 1921. In 1922 the manufacture of tracing cloth was undertaken by another firm which is reported to be controlled by the leading British maker of these goods.

55032—23—1-4——3

General Information.

DESCRIPTION.

Tracing cloth is a plain woven cloth that is processed and coated to make a smooth transparent fabric, glazed on one side but dull finished on the other so as to take ink without blurring. The material of which the constituent cloth is composed is not mentioned in the tariff; some of the higher grades are of linen, but the great majority are of cotton. Tracing cloth is used by draftsmen, architects, and engineers in duplicating drawings of plans for buildings, machinery, and construction work in general. The transparent tracing cloth is placed over the original plan and the lines inked in; it is then placed over sensitized blue-print paper and exposed to sunlight, or such high-power artificial light as the arc or the mercury globe, which quickly turns the paper blue, except where covered by the inked lines on the tracing cloth, thus reproducing the plan in white on a blue ground (or in blue on a white ground, according to the type of paper used); as many prints as desired can thus be secured from one tracing. Tracing cloth is made in widths from 24 to 54 inches, the most usual widths being 30, 36, and 42 inches, with the 36-inch predominating; it is sold usually in rolls of 24 yards, but also, to a lesser extent, in sheets cut to size. Specially prepared tracing paper, although not so durable as the tracing cloth, finds considerable use as a cheaper substitute.

DOMESTIC PRODUCTION.

Materials.—The basic cloth used in the manufacture of tracing cloth is of cotton, in weight and construction equivalent to a light handkerchief lawn. It is entirely of domestic manufacture.

History of the industry.—The manufacture of tracing cloth in the United States was inaugurated about 1906, by a firm which ceased production in 1914 because of inability to manufacture successfully in competition with the English-made product. They state: "This was determined after careful investigation and comparison, and we believe the sole reason is climatic conditions being unfavorable for the manufacture of tracing cloth in this country." Another firm, which started the production of tracing cloth about 1911, discontinued in 1921; a third firm took up the manufacture of these goods in 1922.

Domestic production and consumption.—In order to avoid disclosure of the operations of an individual firm, the production of tracing cloth is not recorded by the census. It is estimated by the trade, however, that the total domestic consumption of tracing cloth is between four and five million square yards and that normally about half of this is produced in the United States and about half imported.

FOREIGN PRODUCTION.

England is the originator and main producer of tracing cloth; the English production is largely controlled by one firm which is an amalgamation of several firms manufacturing various types of filled and coated cloth. This amalgamation controls the world trade in

tracing cloth and produces practically all of that imported into the United States.

IMPORTS.

Imports of tracing cloth in the 10.9 years from August 6, 1909, to June 30, 1920, inclusive, averaged annually 2,339,565 square yards, valued at $484,414, the quantity varying from a low of 1,884,741 square yards in 1919 to a high of 3,296,255 square yards in 1917. Duties collected during the same period averaged annually $173,703, ranging from a low of $96,487 in 1915 to a high of $276,491 in 1920. The value per square yard averaged 20.71 cents, ranging from a low of 16.27 cents in 1911 to a high of 36.59 cents in 1920. On an equivalent ad valorem basis the duty averaged 35.86 per cent, ranging from 30 per cent under the 1913 tariff act to 50.80 per cent in the fiscal year 1913 under the act of 1909. On an equivalent specific basis the duty averaged 7.42 cents per square yard, ranging from 4.89 cents per square yard in 1916 to 10.98 cents per square yard in 1920. In the calendar year 1921 the quantity of imports reached a new low level, 931,528 square yards, but began to return to normal in 1922.

TARIFF HISTORY.

Tracing cloth was first mentioned in the act of 1909 (par. 321), when it was made dutiable at 5 cents per square yard and 20 per cent ad valorem. Under the act of 1913 (par. 254) tracing cloth was dutiable at 30 per cent ad valorem. The 1909 rates were restored in the act of 1922 (par. 907).

Under the act of 1890 tracing cloth was dutiable as countable cotton cloth (T. D. 15140, G. A. 2666), and as such, by reason of its construction and value, it paid ad valorem duties of 40 to 45 per cent. Under the act of 1894 it continued to be assessed as countable cotton cloth until 1895, when the Board of General Appraisers (T. D. 16227, G. A. 3106) decided that while it was possible to count the threads, it could be done only by removing the gelatinous covering, and therefore that tracing cloth was properly dutiable at 35 per cent ad valorem as a manufacture of cotton not specially provided for. Under the act of 1897 tracing cloth was assessed under the new provision for "cotton cloth filled or coated" at 3 cents a square yard and 20 per cent ad valorem. At first this provision was limited to goods in the piece, and tracing cloth cut up into pieces convenient for use was classified as a manufacture of cotton not specially provided for at 45 per cent ad valorem; in 1901 this was held to be erroneous (T. D. 23365, G. A. 5027), and the expression "or otherwise" in the definition of cotton cloth in the Dingley Act was declared to include such goods made from cotton cloth.

COMPETITIVE CONDITIONS.

The competition between imported and domestic tracing cloth has been mainly on the basis of quality. For a long time the American market was monopolized by English manufacturers who sold their goods under special trade-marked brands. These brands became so well known as a guaranty of quality that it has been very difficult to displace them with newer brands put out by a domestic manu-

facturer. A domestic firm that lasted from 1911 to 1921 finally secured nearly half of the domestic market, but though its product was, after considerable experimentation, greatly improved it was able to maintain and enlarge its standing only by persistent advertising. It experienced such keen competition from the long-established English brands of tracing cloth, as well as increasing competition from domestic tracing paper, that it gave up the struggle in 1921. A new domestic firm, established in 1922, will probably have a better chance, as its capital stock is owned by English manufacturers, and they will, presumably, supply the skill and experience necessary to produce the best qualities.

STATISTICAL TABLES.

[1] Tracing cloth was first mentioned in the act of 1909, and imports therefore not recorded prior to the fiscal year 1910.
[2] Imports from Aug. 6, 1909, to June 30, 1910, inclusive.
[3] Average for 10.9 years.
[4] Plus 7 cents a pound if containing cotton of 1⅛-inch staple or longer. (Emergency tariff act of May 27, 1921.)
[5] Includes 34,962 square yards (4,893 pounds), valued at $15,211, paying additional duty of $343 because of the 7 cents a pound surtax levied by the emergency tariff act.
[6] Includes 10,259 square yards (4,157 pounds), valued at $7,347, paying additional duty of $291 because of the 7 cents a pound surtax levied by the emergency tariff act.

The following table shows comparative prices of the principal imported and the nearest comparable domestic tracing cloths. These prices are net, after subtraction of discounts, and were obtained, May 15, 1921, from the three largest dealers in tracing cloths; each of these firms not only imports direct but also handles the domestic article and sells both wholesale and retail.

TABLE 4.—*Tracing cloth—Wholesale and retail prices (per roll of 24 linear yards).*

Firm.	Width in inches.	Imported article.			Domestic article.	
		Approximate landed cost.	Wholesale price.	Retail price.	Wholesale price.	Retail price.
A	30	.....	$14.25	$16.83	$11.26	$17.88

COTTON CLOTH FILLED OR COATED, ALL OILCLOTHS (EXCEPT SILK OILCLOTHS AND OILCLOTHS FOR FLOORS), AND COTTON WINDOW HOLLANDS.

[Paragraph 254, act of 1913; paragraph 907, act of 1922.]

SUMMARY.

The only appreciable import under the above heading is of cotton window hollands. These were formerly almost entirely imported, but within the last decade the domestic production has increased to a point where it not only supplies the bulk of the domestic demand but has built up an export trade that is, temporarily at least, as large in volume and value as that of imports.

The import of cotton oilcloths is very small and the domestic industry has for a good many years not only monopolized the domestic market but obtained a large and increasing market abroad.

GENERAL INFORMATION.

All of the cloths included in the above heading are filled or coated, and practically all are made of cotton. Tracing cloth, also a filled and coated cloth, was provided for under the act of 1913 in the same paragraph at a higher rate of duty, and this is also true of the act of 1922. Some of these filled or coated cloths, particularly oilcloths, are incidentally waterproof, but fabrics primarily waterproof are given separate mention.

DESCRIPTION.

Cotton cloth filled or coated.—A *filled cloth* is one in which all the interstices are filled flush with the top of the weave with a filler of starch or other material, the whole being smoothed down in the operation of the filling machine so as to leave the weave evident through the starch or other materials applied. The filler makes the cloth opaque, or nearly opaque, and adds to the weight and stiffness. The filling substances are varied, among them being starch, china clay, chalk, plaster of Paris, white lead, glue, glauber salts, and glucose. Typical examples of filled cloths are window hollands (specially mentioned in the tariff for reason stated below), buckram and similar cloths stiffened for padding coats, heavily sized grey shirtings, and the like.

A *coated cloth* may be more or less filled in the interstices, but the primary requisite is that the surface be coated with a plaster finish at the expense of the face. The coating materials consist of varnish, paint, pigments, etc. Typical examples of coated cloths are those used in the sign-painting trade and those used for tags, bookbinder's cloth, imitation vellum, "green cloth" (a fabric treated with a solution of copper and used in making artificial flowers), artificial leather, and the like. A coated cloth is usually but not necessarily opaque. For instance, "near glass" is a thin, transparent coated cloth, made of fine yarns in cheesecloth constructions, used for covering merchandise on the counter and for making certain styles of lamp shades. Tracing cloth, which is also transparent, is likewise a coated cloth, but in the acts of 1909 and 1913, also 1922, has been provided for eo nomine at a higher rate than that on other coated cloths.

Cotton window hollands.—Cotton window hollands are used for making roller shades for windows. They are usually plain-woven cotton sheetings (a typical fabric being 38 inches wide, with 60 by 60 ends per square inch, 18s and 20s yarns, weighing 3.24 yards per pound), which are filled to make them more or less opaque, then dyed and glazed by subjection to a beetling process. A portion is bleached instead of dyed.

Cotton window holland is only one type of window-shade cloth. Some domestic window-shade cloth, particularly the cheap 44 by 40 constructions, are finished by simply passing through colored starch. Cloth, such as the 60 by 52, 6.15-yard print cloth, which has been starched and glue sized and then painted, is known as painted shade cloth; if a different color is used on either side it is known as duplicate window shading. The cloth imported from England as "Lancaster window-blind cloth" is of this type. This cloth was held dutiable under the act of 1897 as cotton cloth filled or coated, because the painting completely closes the interstices, whereas cotton window hollands were held dutiable as countable cotton cloth because the filling and beetling did not completely fill the interstices. It was because of this decision that cotton window hollands were specifically mentioned in the act of 1909.

Oilcloths (except silk oilcloths and oilcloths for floors).—The goods so listed are almost entirely cotton oilcloths. Oilcloths are made by giving cloth a coating of solidified linseed oil, either with or without the addition of other materials, such as china clay for weighting and pigments for coloring. The cotton oilcloths are mainly lightweight sheetings which are coated and finished by printing and varnishing. One of the main classes is that known as table, shelf, or wall oilcloth. Enameled oilcloth is produced by baking the coated fabric so as to give a shiny, resistant surface.

Artificial leather.—Artificial leather, which is finding increased uses as a substitute for real leather, is produced on a foundation of cotton cloth, but the composition of the coating and the method of finishing vary widely. In the most typical system the cloth is coated with a solution of pyroxylin (nitrated cotton), castor oil, and other substances; the consistency of the solution and the number of coatings are varied in proportion to the thickness of the base and use for which the finished fabric is intended. From 4 to 16 coats are applied; the solvents used are such as evaporate quickly when exposed to heat, so that successive coats can be applied and dried with little loss of time. After a coating of the required depth is secured, metal rollers or plates are used to stamp the grain or other decorative designs on the softened coating of the fabric. Finishing processes suitable for each type of leather bring out the grain and luster. Artificial leather finds its largest use in covering seats and tops of automobiles and secondarily in upholstering furniture. It is also used for book covers, cardcases, portfolios, traveling bags, suitcases, trunks, toys, baby buggies, sporting goods, caps and leggings, children's hats, motor coats, and a great variety of other articles.

The cotton cloths used as a foundation for artificial leather are mainly sheetings, drills, sateens, and moleskins. Sheeting is used for such purposes as book coverings and linings of bags where no great degree of tensile strength is required. For covering safety razor boxes the material is of the texture of a handkerchief fabric. The

drills and twills are heavier and stronger than sheetings and used for such purposes as upholstering and automobile tops. Sateens are tough and useful where strength and hard surface are required. Moleskin is a form of sateen that is napped on one surface; because of this softness and fullness the artificial leather made on a moleskin base has a plumpness and feel that is very similar to real leather; it is largely used in making traveling bags as well as upholstery. Artificial leather is most largely made in the 50-inch width; in order to allow for shrinking in finishing, the cotton fabrics have to be slightly wider.

DOMESTIC PRODUCTION.

All of the above-mentioned finished cloths, with the exception of some of the less-used specialties, are manufactured extensively, using annually large quantities of domestic grey goods.

Materials.—The basic cotton cloths, while varying in width and weight, are made on plain looms and are produced entirely by domestic manufacturers. China clay is imported from England but the linseed oil, starch, chemicals, and pigments required are obtained locally.

Organization.—The cloth is in most instances purchased by concerns which make a specialty of the finishing by filling and coating. The window holland firms weave their own cloth. The major portion of the production of each class of filled and coated cloth is from a few well-organized large firms of ample capital. Some oilcloth manufacturers have special departments for developing export trade.

Geographical distribution.—Works for converting cotton cloth into oilcloth and artificial leather are found in New Jersey, New York, Massachusetts, Pennsylvania, Maine, Ohio, Illinois, and California. Window hollands are produced in Delaware and Rhode Island.

Domestic production.—The census does not record the total production of all types of filled or coated cotton cloths, but separately enumerates the output of oilcloths made on a cotton back and, starting in 1909, the value of artificial leather produced. Detailed figures are given in Table 5 from which it is seen that in the census years 1904, 1909, 1914, and 1919 the value of oilcloths made on a cotton back was $5,082,648, $7,904,352, $8,520,603, and $15,951,098, respectively; and the value of artificial leather produced in 1909, 1914, and 1919 was $3,448,617, $6,097,293, and $35,026,000, respectively. Between 1914 and 1919 there was a large decrease in the quantity of enameled oilcloth, which was apparently due to substitution of artificial leather in upholstery. The production of cotton window hollands is not recorded by the census but is known to be several times as large as the amount imported.

Domestic exports.—Exports of filled and coated cotton cloths are not recorded separately except in the case of cotton oilcloths. These cloths, listed as oilcloth other than oilcloths for floors, were valued at $666,684 in the fiscal year 1914 and rose to the record value of $3,618,835 in the calendar year 1920. These goods are widely distributed, the main purchasers in 1920 being the Dutch East Indies, Cuba, Argentina, Australasia, Mexico, British India, Holland, United Kingdom, Straits Settlements, and China in the order stated.

Prior to the war there was practically no export of American-made cotton window hollands, but this trade has since been developed to

a point where exports equal imports. It is stated in the trade that the domestic window holland is so much faster in color than the British that in such countries as Australia it finds ready sale at a higher price.

That there are fairly substantial and competitive exports of other types of filled and coated cotton cloths may be gathered from the fact that in the year ended March 31, 1921, Canada imported bookbinder's cloth from the United States to the value of $340,065, as against $143,598 from the United Kingdom.

IMPORTS.

Imports of the cloths grouped together in the statistics as "cotton cloth filled or coated, oilcloths (except silk oilcloths and oilcloths for floors), and cotton window hollands" were first recorded in 1910 under the tariff act of 1909. In the 10.9 years, from August 6, 1909, to June 30, 1920, inclusive, imports averaged annually 2,197,164 square yards, valued at $350,383, ranging from a high of 3,287,594 square yards, valued at $438,299, in 1913 to a low of 438,892 square yards, valued at $144,057, in 1919. The sharp decrease in rate of duty in the act of 1913 was accompanied by a slight decrease in the quantity and value of imports. The revenue collected during these 10.9 years averaged $114,182 annually, ranging from a high of $186,288 in 1913 to a low of $36,014 in 1919. For the calendar year 1921 imports were 525,644 square yards, valued at $183,972, and the duty collected $46,838.

Imports of oilcloths of the kinds so included have been very small and the main item has been cotton window hollands, although there are small imports of the aforementioned "green cloth" and "near glass," and a few others of a more or less novelty character. Bookbinder's cloth, or imitation vellum, is also included; prior to the war this was a rather consistent import, but because of increased domestic production it has declined to small proportions, and imports of such goods are now of the very finest lightweight grades, of which the consumption is not sufficient to interest the domestic manufacturer.

TARIFF HISTORY.

Cotton cloth, filled or coated, was first specifically provided for in the act of 1897 (par. 311). Enameled and other oilcloths of cotton were not included thereunder, as there was a separate provision for oilcloths of all kinds (par. 337), and cotton window hollands were excluded and classed as countable cotton cloth on the ground that the interstices were not substantially filled; in other words, that they were not entirely opaque.

In the act of 1909 (par. 321) there was inserted a provision for "Cotton cloth, filled or coated, all oilcloths (except silk oilcloths and oilcloths for floors), and cotton window hollands, 3 cents per square yard and 20 per centum ad valorem; * * *."

This provision was retained unchanged in the act of 1913 (par. 254) except that the rate of duty was made a flat 25 per cent ad valorem.

This provision was also retained in the act of 1922 (par. 907) but the rate of duty was made the same as in the act of 1909.

55032—23—I-4——4

COMPETITIVE CONDITIONS.

Cotton oilcloths.—The American export of cotton oilcloths was large before the war and has since increased greatly. Imports were and are very small. The basic cloths are usually fully as cheap in the United States as abroad, and judging from the great excess of exports over imports it seems evident that the large scale domestic production methods enable domestic oilcloth manufacturers to produce the finished goods at a lower price than abroad.

Cotton window hollands.—Of the cloths grouped together under the heading of this section the only one imported in any appreciable quantity is cotton window holland. Imports are mainly from one Scotch firm which has a long-established trade. This firm produces a very good grade of window hollands in white, cream, ecru, "linen," drab, and other light shades; it finishes its goods slowly and carefully with old-fashioned wooden faller beetles, which, in conjunction with the filled cloth being in a slightly damp condition when the beetling is started, permits the production of a smooth finished fabric with the interstices in the cloth substantially closed. These wooden faller beetles strike the cloth in the roll at the rate of about 50 to 56 strokes a minute.

One domestic manufacturer uses wooden faller beetles and produces mainly the light shades such as are imported. Another beetles with steel hammers, operated a great deal faster, about 350 strokes a minute, and produces for the most part green or blue shades of a good depth. He piece-dyes with mineral colors, the particles of which are very finely divided, and uses gums to assist suspension in the dye bath. These mineral-dyed goods are much faster to sunlight than any goods produced abroad, so much so that there has been built up an export trade with British possessions, a trade now fully as large as, if not larger than, the import trade.

Cotton window hollands are made from ordinary grey sheeting, averaging around 20s yarns, and such cloth is usually as cheap in the United States as in the United Kingdom. Although relative finishing costs are not known it would seem, judging from prices of the finished goods, that the domestic costs are now as low as, if not lower than, the foreign.

Both imports and exports appear to be on the basis of quality rather than price. Scotch window hollands, of the lighter shades mainly, sell in the United States largely on the basis of established reputation. American window hollands, mainly of the deeper-dyed shades, sell in Australasia because the colors are faster than those offered by the United Kingdom.

STATISTICAL TABLES.

TABLE 5.—*Cotton-back oilcloths and artificial leather—Production in United States.*

[From Federal Census.]

	1904	1909	1914	1919	1921
Oilcloths (made on cotton back):					
Enameled—					
Square yards	11,574,986	17,338,440	18,357,097	8,460,738	[1] 3,007,000
Value	$1,542,467	$2,265,146	$2,495,255	$3,421,188	[1] $1,015,000
Table, wall, shelf, and stair—					
Square yards	38,026,083	61,168,777	59,358,872	39,132,641	[1] 64,196,000
Value	$3,540,181	$5,639,206	$6,025,348	$12,529,910	[1] $14,389,000
Artificial leather:					
Square yards	[2]	[5] 11,869,875	[3]	[3]	[4]
Value	[2]	[5] $3,448,617	[6] $6,097,293	$35,025,714	$15,589,000

[1] Includes oilcloth made by one establishment engaged in manufacturing other products of chief value.
[2] Not recorded.
[3] The practice of the Bureau of the Census is to classify mills according to the predominant product. In the 1919 census, artificial leather was recorded to the extent of 13,632,501 square yards, valued at $8,743,748, under the general classification of "Oilcloth and linoleum," and to the value of $26,281,966, quantity not stated, under the general classification of "Upholstering materials not elsewhere specified." The total value of the artificial leather produced in 1919 was therefore $35,025,714, but the total quantity corresponding thereto was not recorded.
[4] In the 1921 census, artificial leather was recorded to the extent of 283,000 square yards, valued at $73,000, under the general classification of "Oilcloth and linoleum," and to the value of $15,516,000, quantity not stated, under the general classification of "Upholstering materials not elsewhere specified." The total value of the artificial leather produced in 1921 was therefore $15,589,000, but the total quantity corresponding thereto was not recorded. The great bulk of the so-called artificial leathers is made with pyroxylin coatings in establishments devoted primarily or exclusively to their manufacture, and only a minor portion is made, partly with pyroxylin and partly with linseed oil coatings, in establishments devoted primarily to oilcloths.
[5] Shown on page 200, Table 9, of Volume X of 1910 census; apparently total of all artificial leather produced in 1909.
[6] Recorded as "imitation leather, leatheroid," under general heading of "Upholstering materials, not elsewhere specified." This is apparently not the complete total for all artificial leather produced, as there is no record of that produced in establishments engaged primarily in the manufacture of "Oilcloth and linoleum."

1922	907	* * * cotton window hollands, all oilcloths (except silk oilcloths and oilcloths for floors), and filled or coated cotton cloths not specially provided for.	3 cents per square yard and 20 per cent ad valorem.

COURT AND TREASURY DECISIONS.

The word "filled" as used in paragraph 311 of the act of 1897 was declared to be a manufacturing rather than a commercial term, and not to be confined in its meaning to such goods as were weighted with a foreign substance, usually an inorganic material, to give them a fictitious solidity, in which sense it was formerly used in England; the filling might be starch alone. It was furthermore declared, however, that whatever substance was used to constitute cotton cloth filled, such quantity must be used as substantially to close the interstices and make a plain surface. Scotch hollands or kings

hollands used for window shades and stiffened with 20 per cent in weight of starch which did not substantially close the interstices, were held to come within the countable cotton cloth clauses (United States *v.* Pinney, 105 Fed., 934 of 1900). Cotton cloth which had been subjected to several coats of paint until the interstices were completely filled, giving it an appearance somewhat similar to oilcloth, and known in trade as Lancaster window blind cloth, was held to be cotton cloth filled or coated under paragraph 321 of the act of 1909 (Shallus *v.* United States, 1 Ct. Cust. Appls., 556 of 1911), as was also woven cotton cloth coated with an artificial silk flock, the artificial silk constituting the material of chief value. The manner in which the flock was attached by a binding to the surface of the fabric was declared to make a coating only, since the artificial silk did not enter into the real web of the goods but might easily be scraped from the surface without otherwise affecting the structure of the fabric (Knauth *v.* United States, 2 Ct. Cust. Appls., 479 of 1912).

But window curtains cut in lengths of 6 feet from cotton hollands and hemmed and ready for the sticks to be inserted were held to be excluded from paragraph 321 of the act of 1909 because the goods were not fabrics or piece goods within the intended scope of the words "cotton window hollands" and, furthermore, excluded from the countable provisions because of being partly completed window curtains, and therefore "an article, finished or unfinished, made from cotton cloth," within paragraph 332 (United States *v.* Anderson, 3 Ct. Cust. Appls., 191 of 1912). So-called green cloth, treated with a solution of copper and wax, was held dutiable under the provision for cotton cloth filled or coated in the act of 1913 (T. D. 34062 of 1914), as was green cloth which had been apparently treated or coated with some substance which made it smooth and slightly stiff. (Abstract 37257 of 1915.)

WATERPROOF CLOTH OF COTTON OR OTHER VEGETABLE FIBER.

[Paragraph 254, act of 1913; paragraph 907, act of 1922.]

SUMMARY.

The production of waterproof cloths in the United States is large and constantly increasing. There are no data as to the extent of this output, but it is known to run into millions of dollars.

Imports of waterproof cloth are negligible, averaging during the 1911–1920 (fiscal year) decade only $84,235 annually, and for the calendar year 1921 only $77,892, as shown in Table 8. Imports are confined mainly to special types on which there is not sufficient demand to attract the domestic manufacturer. The most consistent item in this small trade consists of a heavy cloth, used mainly for automobile tops, sides, and seat covers, that is not processed in any way but which gains its waterproof quality from the close weaving of coarse yarns.

GENERAL INFORMATION.

DESCRIPTION.

Waterproof cloths under paragraph 254 of the act of 1913 and paragraph 907 of the act of 1922 include all made of cotton or other vegetable fiber, with or without the addition of india rubber, not otherwise specially mentioned.

Waterproof cloths are used for many purposes and include types used for raincoats, auto tops, dress shields, infants' wear, and hospital use. Any cloth which is impervious to water, or nearly so, and intended to turn water might be classed as a waterproof cloth. Some fabrics invoiced as waterproof cloths and held to be so dutiable are simply close-woven cotton cloths which have undergone no special treatment, and others are made by cementing together two cloths (such as the duplex fabric made of a printed cloth and a dyed cloth and used for raincoats) that are otherwise not waterproof. The majority of waterproof cloths have, however, been subjected to special finishing processes, the nature and extent of which are dependent on the service expected of the particular goods.

DOMESTIC PRODUCTION.

The great bulk of the waterproof cloths used in the United States are of domestic manufacture and finish. There are no figures as to the exact extent of the domestic industry, but it is known to be large and increasing. Imports are relatively negligible.

Materials.—Aside from the basic cotton cloths, practically all of which are of domestic manufacture, the waterproofing industry uses various chemicals, salts, oils, fats, wax, paraffin, and rubber. Linen, instead of cotton, cloth is used as the foundation material in some cases.

Equipment.—The majority of the domestic production is from large and well-equipped plants. Most of the large rubber companies finish quantities of this material, which they sell in the finished garment.

Methods of production.—The methods [4] of preparing fabrics in order to make them water-resistant are:

1. Impregnation with metallic salts.
2. Coating with oils, fats, and wax.
3. Coating with solutions of rubber.
4. Superficial solution by means of Schweitzer's reagent.

The first method finds application in the dressing of sailcloth and other heavy fabrics. The material is impregnated with alum and acetate of lime, and is then entered into a fixing bath containing waterglass. For some classes of goods the latter bath consists of a soap solution, in which case an insoluble aluminum or lime soap is formed in the fabric.

The second method is used for rain cloths, sign cloths, imitation leather, and the like. The fabric is passed between hot rollers and then over a block of wax. By another method the wax is dissolved in benzine and the fabric padded with this solution. As the latter method is much more expensive, it is generally limited to ladies' high-class dress goods.

In the third method the rubber is dissolved in carbon disulphide, chloroform, or the like. The goods may be either coated or padded with the solution. Gossamer cloth, mackintosh cloth, bathing caps, dress shields, infants' wear, etc., are examples of this class of fabric.

The fourth method has found application in the manufacture of bookbinders' cloth. It consists in passing cotton cloth through an ammoniacal solution of cupric oxide, which dissolves the cotton on the surface to a slight extent. A passage between hot rollers completes the operation.

[4] This classification is given in an article printed in Posselt's Textile Journal of August, 1920.

Geographical distribution.—Judging from establishments listed as engaged in this trade, the waterproofing of cotton cloths is carried on largely in New York, Massachusetts, Connecticut, Delaware, and Ohio.

Domestic production.—The production of waterproof cloths in the United States is large and constantly increasing. There are no data as to the extent of this output, but it is known to run into millions of dollars.

IMPORTS.

Imports of waterproof cloth of cotton or other vegetable fiber were first enumerated, separately from waterproof cloths in general, in the fiscal year 1898. In the 23 years, 1898–1920, imports of waterproof cloth of cotton or other vegetable fiber averaged annually 123,290 square yards, valued at $50,671, with a record import of 347,230 square yards, valued at $115,292, in 1910. The revenue received during these 23 years averaged $17,023, with a record of $57,781 in 1910.

It may be noted that the average value per square yard of imported waterproof cloth is very high, almost twice that of countable cotton cloths, and only exceeded by that of cotton pile fabrics. During the 23 years for which records are available, imports of waterproof cloth of cotton or other vegetable fiber averaged 41.10 cents per square yard, varying from a low of 31.57 cents in 1911 to a high of 73.91 cents in 1919. For the calendar year 1921 there were imported 107,921 square yards, valued at $77,892, the value per square yard being 72.18 cents, and the duty collected $19,602.

The equivalent ad valorem rates of duty have varied from 25 per cent under the 1913 act to 51.67 per cent in 1911, with a 23-year average of 33.59 per cent. The equivalent specific duty has varied from 6.74 cents in 1914 to 18.48 cents in 1919, with a 23-year average of 13.81 cents per square yard. During the calendar year 1921 the equivalent specific duty was 18.16 cents per square yard.

The bulk of the small imports of waterproof cloth of cotton or other vegetable fiber gain their water-resisting qualities by very close weaving and have not been subjected to any waterproofing process. These imports are usually in small quantities of any one type, as they are designed for special purposes. The most consistent and largest import of this type is a heavy canvas-like fabric, plain woven, of dyed or bleached yarns, largely in mixtures of tan shades and white or plain colors. It is used for automobile tops, sides, and seat covers. While some fabrics of this type are produced in the domestic industry, the variety imported is of the highest quality and has never been used in sufficient quantities to attract the domestic manufacturer. The recent and more general use of closed cars has tended to further reduce the demand for these fabrics and, aside from imported cars, their use is confined mainly to special cars, so-called "sport models," of the highest grade.

While the bulk of the imports of waterproof cloths of cotton or other vegetable fiber consist of the above-mentioned unprocessed auto-top cloth, there are from time to time smaller imports of various processed cloths, with or without india rubber.

TARIFF HISTORY.

"Waterproof cloth" has been given specific mention in tariff acts for more than half a century. In the act of 1897 (par. 337) the eo nomine provision was limited to "waterproof cloth, composed of cotton or other vegetable fiber, whether composed in part of india

rubber or otherwise, 10 cents per square yard and 20 per cent ad valorem." This provision remained the same in the act of 1909 (par. 347). In the act of 1913 (par. 254) it was changed to "waterproof cloth composed of cotton or other vegetable fiber, or of which cotton or other vegetable fiber is the component material of chief value or of cotton or other vegetable fiber and india rubber, 25 per cent ad valorem." In the act of 1922 the wording was simplified to "waterproof cloth composed wholly or in chief value of cotton or other vegetable fiber, whether or not in part of india rubber," and the duty was made compound at 5 cents per square yard and 30 per cent ad valorem.

TARIFF CONSIDERATIONS.

The necessity of a separate tariff provision for "waterproof cloth of cotton or other vegetable fiber" is doubtful, since the small imports are mainly of an unprocessed cloth that should logically be dutiable under the progressive rates of duty applied to other countable cotton cloths. It should be noted that oilcloth and various other coated or filled cloths are incidentally waterproof by reason of such coating or filling

STATISTICAL TABLES.

1922	907	* * * waterproof cloth composed wholly or in chief value of cotton or other vegetable fiber, whether or not in part of india-rubber.	5 cents per square yard and 30 per cent ad valorem.

Court and Treasury Decisions.

The term "waterproof cloth" has been interpreted to be cloth which is practically waterproof (Abstract 25485, T. D. 31568, of 1911, following United States *v.* Brown, 136 Fed., 550, so classifying cravenette). A cloth coated with india rubber, which was known as jaconette sheeting, and which upon testing withstood water from running through it for a period of more than three hours, was held by the Board of General Appraisers to be dutiable as waterproof cloth. In other cases waterproof cloth has been declared to be cloth impervious to water or nearly so (Abstract 27706, T. D. 32224, of 1912, holding cloths which when formed into a sack do not prevent water from seeping through are not waterproof; and United States *v.* Walker, 5 Ct. Cust. Appls., 215, of 1914, holding that cloth having on one side the appearance of velvet and on the other side a smooth rubberlike appearance and feel come within paragraph 347 of the act of 1909 as waterproof cloth; and cases therein cited).

The provision in the acts of 1897 (par. 337) and 1909 (par. 347) for "waterproof cloth composed of cotton or other vegetable fiber, whether composed in part of india rubber or otherwise," was construed to mean "whether composed in part of india rubber or not" and not as relating to other materials than india rubber (Gartner *v.* United States, 154 Fed., 957, of 1907; United States *v.* Vandegrift, 4 Ct. Cust. Appls., 226, of 1913). The 1909 provision was held not to include waterproof cloth in chief value of india rubber (Kenyon Co. *v.* United States, 4 Ct. Cust. Appls., 344, of 1913). This decision led to the change in paragraph 254 of the act of 1913:

Waterproof cloth composed of cotton or other vegetable fiber, or of which cotton or other vegetable fiber is the component material of chief value or of cotton or other vegetable fiber and india rubber.

COTTON PILE FABRICS, AND MANUFACTURES THEREOF.

[Paragraph 257, act of 1913; paragraph 910, act of 1922.]

SUMMARY.

Cotton pile fabrics may be divided into two broad classes: (1) Velveteen, corduroy, velvet, and plush, and (2) Turkish toweling and other terry woven fabrics. The production of both classes of fabrics has been steadily increasing in the United States.

Imports of cotton pile fabrics have fluctuated, but as a whole have tended to decrease during the past 20 years and to form a smaller and smaller proportion of the domestic consumption. Imports are mainly of velveteen of a superior quality, mainly hand-cut goods, and smaller quantities of plush specialties. As the domestic industry increases in skill as well as in output, the market for foreign goods is becoming more and more restricted. Competition is more largely on quality than price.

GENERAL INFORMATION.

DESCRIPTION AND METHODS OF MANUFACTURE.

Cotton pile fabrics constitute the leading class of cotton cloths provided for eo nomine.

Pile fabrics consist of a foundation cloth covered in whole or in part by short projecting ends or loops made with an extra set of threads. Technically, pile fabrics are divided according to method of construction into two classes: (1) Filling piles, such as velveteen and corduroy, and (2) warp piles, such as velvet, plush, and Turkish toweling. In all cases the foundation fabric requires its own set of warp and of filling threads, and the pile, whether warp or filling, is made from an additional set of threads. Filling pile is always cut, whereas warp pile may be either cut or loop (uncut).

In filling-pile fabrics the warp and one filling is used to produce the ground, which may be either plain woven or twilled, whereas the extra or pile filling is floated loosely over the surface and bound into the ground at regular intervals to form longitudinal lines or races. These floats are afterwards cut near their center and brushed up to make a pile covering the surface. Velveteens, also known as velverets, are woven so that the cut pile covers the ground uniformly, whereas corduroys are woven so that the cut pile forms ribs or "cords."[5] Velveteens run from 19 to 36 inches in width, the narrower widths being woven two or more in a loom and having split selvages. For dress and trimming purposes, velveteens are piece-dyed in solid colors. For upholstery purposes the piece-dyed goods may be printed, embossed, or stamped with designs from a heated iron cylinder. Panel and stripe patterns are also made by cutting a raised figure on an uncut ground or vice versa, painting by hand, or burning by the pyrogravure process where the operator uses a pantograph-guided platinum stylus heated to redness to burn out the pile according to the pattern desired. In addition to ordinary dress and upholstery purposes, velveteen is used for handbags and shoe tops, and for lining fine jewelry and silverware boxes.

[5] Velveteens can be made by special cutting to look like corduroys. These are termed "hollow-cut velveteens."

Corduroys are velveteen cords, which are produced by binding the filling-pile floats into the foundation fabric in straight lines with intervals so that when cut they form ribs or cords running lengthwise of the fabric. These ribs may be of different sizes and have round or flat tops. The finer varieties of corduroys, usually made in fine yarns with a plain back, are used for children's clothing and dress fabrics. Corduroys made of coarser yarns, usually with a twill back, are noted for their exceptional wearing qualities and are used for riding trousers and skirts, and for suits of men engaged in rough labor and field sports. These goods are usually woven to finish, after piece-dyeing, in 27 to 30-inch widths. Some velveteen cords are used for upholstery, being printed, after dyeing, in elaborate floral designs.

Velveteens and corduroys come from the loom as unbleached, uncut fabrics, and have to undergo a variety of processes before they are ready for sale. Prior to the cutting operation a thin coating of lime paste is applied to the face and dried, the cloth then passed through a brushing machine which loosens the filling floats so the knife can readily pass underneath, and then back-starched, so that the filling-pile threads will not be pulled out in the operation of cutting, and again dried. The floats are then cut, usually by machinery which employs either a blade or disk (circular) cutter. Hand cutting gives better results than machine cutting but is more laborious and expensive.

In hand cutting the operator uses a special knife equipped with a guide and cuts the races, or longitudinal series of floats, one after the other, as he walks up and down beside a long table upon which the cloth is stretched.[6] On the completion of the cutting operation the stiffening substances previously applied are removed by scouring and the cloth dried. Any holes made during the cutting are repaired. The pile is then brushed up and rubbed, superfluous fibers removed by shearing or singeing, and the cloth subjected to the dyeing process, after which it is again dried, brushed, and rubbed. The operations subsequent to weaving constitute a large proportion of the total cost of manufacture.

Velveteens and corduroys are rather difficult fabrics to produce successfully and require a large proportion of skilled labor. The slightest defect in weaving will show in the finished article, and many goods are spoiled after leaving the loom, so that the percentage of seconds is unusually large. These goods are woven with a comparatively small number of ends, say 40 to 88 to the inch, but have an excessive number of picks, say 150 to 600 to the inch. Because of this high pickage the rate of production is extremely slow, also the looms have to be extra strong, and the warp held under great tension.

Velveteens, as a rule, cost more and involve a higher percentage of labor than corduroys. Velveteens are made of finer yarns, weave

[6] Corduroys are always machine cut, and the hand cutting of velveteens has practically been eliminated in this country. Machine cutting also predominates abroad, but is not general as in this country, and many of the better grades of velveteens imported are hand cut. The superiority in appearance of these hand-cut foreign fabrics is one of the main reasons for their continued import.

slower, are more expensive to cut, and the finishing requires more work and care.[7]

Cotton plush is usually woven as a double-pile fabric. In this case there are woven on each loom simultaneously two cloths, one above the other, which are connected by the alternate interlacing of the warp-pile threads. A knife traveling automatically from side to side of the loom severs the warp-pile threads halfway between the two foundation fabrics and leaves each fabric with its own cut pile. Velvet is technically similar to plush except that the pile is shorter and denser. There is very little cotton velvet made, however, and goods sold under this name are usually velveteens, which are called "cotton velvets" to distinguish them from the "velvets" of silk, which are true warp piles.[8] In the same way the terms "cotton plush" or "weft plush" are sometimes applied to velveteens with an extra long pile. Cotton warp piles are rarely woven over wires, as this method of manufacture is too expensive for any but silk velvets woven in countries having cheap labor.

Turkish toweling is a terry (loop) cloth, made with warp pile, that is woven by a method different from any of the foregoing. It is made on looms with a special reed motion and warp easing arrangement, so that a certain number of picks are first inserted and only partially beaten up, and then all of the picks together beaten up over the intervening distance to the fell of the cloth; the filling picks slide on the tight ground warp and hold and carry with them the slack pile warp which is thereby caused to form loops on one or both sides of the cloth.

Paragraph 257 of the act of 1913 covered all cotton pile fabrics in the piece, also manufactures thereof, with the exception of wearing apparel, articles of cotton chenille, and towels, bath mats, polishing cloths, and wash rags, all of which were specially provided for elsewhere. The imports recorded under the head of manufactures of cotton pile fabrics were negligible in amount, consisting of more or less sporadic imports of portieres and miscellaneous articles. Paragraph 910 of the act of 1922 covers all cotton-pile fabrics in the piece, and all manufactures thereof with the exception of wearing apparel. Because of the inclusion of articles of cotton chenille, Turkish towels, etc., the record of imports under the head of manufactures of cotton pile fabrics will doubtless be somewhat increased under the act of 1922.

DOMESTIC PRODUCTION.

The domestic production of pile fabrics has been increasing steadily in quantity and in range of varieties. The output of cotton vel-

[7] One domestic manufacturer states: "Varying with the width of the cloth and the speed of the loom, a weaver can take care of from 6 to 8 looms on velveteen and from 6 to 18 looms on corduroy. For the same width of loom the speed will be the same in each case, and the rapidity with which the cloths are woven will depend on the relative number of picks to the inch. From 75 to 85 per cent of the theoretical production is usually obtained. The percentage of seconds, shorts, remnants, irregulars, and "pounds" will vary from a maximum of 30 per cent and command a market at from 20 to 50 per cent reduction on the price of firsts according to classification." Another domestic manufacturer states: "One weaver can run 12 automatic looms on velveteens and 16 on corduroys; the speed of the loom is about 150 picks per minute. The production obtained and the percentage of seconds vary considerably in different mills. In all cases, however, the amount of velveteen seconds is much larger than corduroys." A third manufacturer states: "Average looms to a weaver, 12 to 16. Speed of loom, 150. Per cent of theoretical production usually obtained, conservatively, 80 per cent. Usual per cent of seconds, 10."

[8] One manufacturer states: "We understand that the trade designation of velveteen was adopted in this country owing to the existence of statutory prohibition in several States of the use of the word 'velvet' in connection with any pile fabric not made of silk." Another manufacturer states: "English 'cotton velvets' are filling pile fabrics which would be known in this country as 'velveteens.' In the last few years there has been developed in this country a real 'cotton velvet' that is woven just like a silk velvet, but with mercerized cotton yarns substituted for silk. A small amount of business is done on this cloth."

veteen, corduroy, velvet, and plush amounted to 29,128,703 square yards, valued at $8,540,143 in 1914, and to 40,183,780 square yards (26,175,547 pounds), valued at $36,673,551, in 1919. The output of Turkish toweling and other terry woven fabrics, which in 1919 was not separately recorded, amounted in 1919 to 31,948,062 square yards (17,444,220 pounds), valued at $14,477,643.

Equipment.—The weaving, cutting, and finishing processes require special machinery. All of the machinery required is obtainable in this country, although a small amount is still imported because of special design or because of individual preferences.

Organization.—The majority of the domestic mills producing pile fabrics of cotton are self-contained, buying cotton and turning out the finished fabric ready for use. A few follow the predominant European practice of buying their yarns and of having the goods finished outside. Many of the domestic mills produce other fabrics in addition to pile fabrics.

Geographical distribution.—The production of cotton velveteens, corduroys, and plushes is carried on extensively in Pennsylvania, Rhode Island, Massachusetts, New York, Connecticut, and Tennessee. Toweling and terry weaves are produced largely in North Carolina, Georgia, Pennsylvania, New Hampshire, Massachusetts, and New York.

Domestic exports.—The export trade in cotton pile fabrics is not separately recorded, being included in the figures for "all other manufactures of cotton." Judging from such partial figures as are obtainable from the import records of other countries, it would seem that in the period since the war domestic exports have exceeded imports. An indication is afforded by the Canadian records of imports; for the fiscal year ended March 31, 1922, they showed imports from the United States of cotton velvets, velveteens, and plush fabrics, not otherwise provided for, to the extent of 412,393 yards, valued at $419,054. Canada also imported from the United States, in the same year, cotton towels and toweling valued at $374,454, but the record does not indicate how much of this was terry woven.

INTERNATIONAL TRADE.

International trade in cotton pile fabrics was, prior to the war, supplied mainly by shipments from the United Kingdom, Germany, and France, with smaller amounts from Austria, but practically none from other countries. The largest pre-war importers were Russia and China, followed by the United States, Germany, Austria, Italy, Canada, and France. Oldham, in England, was and probably continues to be the largest center of manufacture. Crefeld, in Germany, was the most important continental center for the dyeing and finishing of cotton as well as of silk pile fabrics.

Since 1915 international trade in cotton pile fabrics has been supplied mainly by the United Kingdom and the United States.

IMPORTS.

With the continued development of the domestic industry the field for foreign pile fabrics has become narrowed down mainly to those of exceptional high grade and to specialties.

The United Kingdom has always been the main source of imports of cotton pile fabrics, but for several years prior to the war its supremacy was being threatened by increasing shipments from Germany. The small French trade was also increasing, but with the exception of small amounts from Austria there were practically no imports from other countries. During the World War imports were almost exclusively from the United Kingdom. It continues to be the main source, although imports have been resumed from France and Germany.

During the 30 fiscal years 1891–1920, inclusive, covering five tariff acts, imports for consumption of cotton pile fabrics averaged 5,250,351 square yards, valued at $1,815,449. The record import consisted of 15,917,514 square yards, valued at $4,181,038, in 1897. In the calendar year 1921 imports dropped to a new low level of 210,954 square yards, valued at $270,788.

The largest amount of revenue, $1,920,411, was collected in 1897, and the least, $109,522, in the calendar year 1921. The equivalent ad valorem rate of duty for the 30-year period averaged 54.27 per cent, ranging from a high of 71.18 per cent in 1899 to a low of 40 per cent under the act of 1913, and the equivalent specific rates of duty averaged 18.76 cents per square yard, ranging from a low of 12.06 cents per square yard in 1897 to a high of 43.23 cents per square yard in 1920. For the calendar year 1921 the ad valorem rate of duty averaged 40.44 per cent, and the equivalent specific rate 51.92 cents per square yard.

It may be noted that in 1891 an increase of duty from a flat 40 per cent ad valorem in 1890 to an average equivalent of 53.02 per cent in 1891 was accompanied by an increase in the recorded value of imports from $845,543 to $1,474,777, but as the classification was in the act of 1890 extended to cover all cotton pile fabrics instead of the "cotton velvet" of the preceding tariff, the actual effect of the higher rates is obscured. In 1895 a substantial decrease in the rate of duty was accompanied by a large increase over the unusually small imports of the preceding year. In 1898 a substantial increase in the rate of duty was accompanied by a large decrease from the record imports of the preceding year, but in the succeeding years imports were again large. The act of 1909 reenacted the pile fabric wording and rates of the act of 1897; imports showed a slight increase in 1910, and in 1911 increased to 4,189,917 square yards. The decrease of the rate of duty to 40 per cent in the act of 1913 apparently had little effect on imports, in fact imports in 1914 were somewhat less than in 1913. It is remarkable that during the seven years, 1911–1917, imports were almost stationary at approximately 4,000,000 to 4,500,000 square yards a year. After 1917 imports of cotton-pile fabrics were greatly reduced and though this was an effect of the war, the domestic industry has increased to a point where exports exceed imports.

TARIFF CONSIDERATIONS.

Pile fabrics are subject to the caprices of fashion and the demand for different varieties and grades fluctuates so from year to year that variations in volume and value of imports can not be used as accurate measures of the effect of tariff changes. It is evident, from a study of the imports given in Table 11, that any large decrease in the rate

of duty results in a temporary increase of imports, and any large increase in the rates of duty results in a temporary decrease in imports, but such increases or decreases are rarely sustained over succeeding years, and equally wide fluctuations are to be found in non-tariff years. The tariff on pile fabrics remained unchanged from 1898 to 1913, inclusive, and it is to be noted that although there was a tendency to decline down to 1910, imports increased in 1911 and then remained almost stationary for seven years, without regard to a decrease in duties in 1913. Imports were more than six times as large in 1899, with an equivalent rate of 71.18 per cent ad valorem, as they were in 1909, with an equivalent rate of 54.69 per cent ad valorem, although the tariff wording and rates were the same in both years. Imports were larger in 1913 under an equivalent 50.38 per cent ad valorem than they were in 1914 under an equivalent 44.32 per cent ad valorem. A study of imports and duties would seem to show that the exact height of the duty, within reasonable limits, is yearly becoming of less importance. The domestic industry has become so strong that foreign countries can hardly expect to compete on the American market with goods of the class made in the United States; imports have therefore become mainly supplementary and consist of high-class goods, goods that are sold in small quantities of any one style, and specialties involving such a large proportion of labor that American mills do not care to attempt them.

STATISTICAL TABLES.

[1] Cotton velvets, velveteens, corduroys, plushes, etc.
[2] Includes velvet, quantity not given, valued at $478,449, on which $191,379.60 duty was assessed.
[3] Value per unit covers only that portion of the 1891 imports for which quantity is known.
[4] Imports of terry cloth (but not manufactures of) are included in the records for 1910 and subsequent years. They are not included in the years prior to 1910, as they were dutiable as "Manufactures of cotton not otherwise provided for" under the acts of 1890 and 1894, and as countable cotton cloth under the act of 1897.
[5] Plus 7 cents a pound if containing cotton of 1⅛-inch staple or longer. (Emergency tariff act of May 27, 1921.)
[6] Includes 23,174 square yards (17,243 pounds), valued at $35,445, paying additional duty of $1,207 because of the 7 cents a pound surtax levied by the emergency tariff act.
[7] Includes 33,464 square yards (13,682 pounds), valued at $34,780, paying additional duty of $958 because of the 7 cents a pound surtax levied by the emergency tariff act.

[1] Prior to 1898 manufactures of pile fabrics were dutiable under the basket clause for "All other manufactures of cotton not specially provided for," and there are no records as to the amounts brought in.

[2] Not recorded.

[3] Plus 7 cents a pound if containing cotton of 1⅛-inch staple or longer. (Emergency tariff act of May 27, 1921.)

[4] Includes 2,939 pounds, valued at $7,740, paying additional duty of $206 because of the 7 cents a pound surtax levied by the emergency tariff act.

[5] Includes 4,111 pounds, valued at $14,330, paying additional duty of $288 because of the 7 cents a pound surtax levied by the emergency tariff act.

Cotton pile fabrics, and manufactures thereof—Rates of duty.

Act of—	Par.	Tariff classification or description.	Rate of duty.
1883	325	* * * cotton velvet	40 per cent ad valorem.
1890	350	Plushes, velvets, velveteens, corduroys, and all pile fabrics composed of cotton or other vegetable fiber, not bleached, dyed, colored, stained, printed, or painted.	10 cents per square yard and 20 per cent ad valorem.
		All such goods if bleached	12 cents per square yard and 20 per cent ad valorem.
		If dyed, colored, stained, painted, or printed	14 cents per square yard and 20 per cent ad valorem.
		But none of the foregoing articles in this paragraph shall pay a less rate of duty than.	40 per cent ad valorem.
1894	259	Plushes, velvets, velveteens, corduroys, and all pile fabrics composed of cotton or other vegetable fiber, not bleached, dyed, colored, stained, painted, or printed.	Do.
		On all such goods if bleached, dyed, colored, stained, painted, or printed.	47½ per cent ad valorem.
1897	315	Plushes, velvets, velveteens, corduroys, and all pile fabrics, cut or uncut; any of the foregoing composed of cotton or other vegetable fiber, not bleached, dyed, colored, stained, painted, or printed.	9 cents per square yard and 25 per cent ad valorem.
		If bleached, dyed, colored, stained, painted, or printed	12 cents per square yard and 25 per cent ad valorem.
		Provided, That corduroys composed of cotton or other vegetable fiber, weighing 7 ounces or over per square yard, shall pay a duty of.	18 cents per square yard and 25 per cent ad valorem.
		Provided further, That manufactures of articles in any form including such as are commonly known as bias dress facings or skirt bindings, made or cut from plushes, velvets, velveteens, corduroys, or other pile fabrics composed of cotton or other vegetable fiber, shall be subject to the foregoing rates of duty and in addition thereto.	10 per cent ad valorem.
		Provided further, That none of the articles or fabrics provided for in this paragraph shall pay a less rate of duty than.	47½ per cent ad valorem.
1909	325	Plushes, velvets, velveteens, corduroys, and all pile fabrics, cut or uncut, whether or not the pile covers the entire surface; any of the foregoing composed of cotton or other vegetable fiber, except flax, not bleached, dyed, colored, stained, painted, or printed.	9 cents per square yard and 25 per cent ad valorem.
		If bleached, dyed, colored, stained, painted, or printed	12 cents per square yard and 25 per cent ad valorem.
		Provided, That corduroys composed of cotton or other vegetable fiber, weighing 7 ounces or over per square yard, shall pay a duty of.	18 cents per square yard and 25 per cent ad valorem.
		Provided further, That manufactures or articles in any form, including such as are commonly known as bias dress facings or skirt bindings, made or cut from plushes, velvets, velveteens, corduroys, or other pile fabrics composed of cotton or other vegetable fiber, shall be subject to the foregoing rates of duty and in addition thereto.	10 per cent ad valorem.
		Provided further, That none of the articles or fabrics provided for in this paragraph shall pay a less rate of duty than.	47½ per cent ad valorem.
1913	257	Plushes, velvets, plush or velvet ribbons, velveteens, corduroys, and all pile fabrics, cut or uncut, whether or not the pile covers the entire surface; any of the foregoing composed wholly or in chief value of cotton or other vegetable fiber, except flax, hemp, or ramie; and manufactures or articles in any form, including such as are commonly known as bias dress facings or skirt bindings, made or cut from plushes, velvets, velveteens, corduroys, or other pile fabrics composed of cotton or other vegetable fiber, except flax, hemp or ramie.	40 per cent ad valorem.
1922	910	Pile fabrics, composed wholly or in chief value of cotton, including plush and velvet ribbons, cut or uncut, whether or not the pile covers the whole surface, and manufactures, in any form, made or cut from cotton pile fabrics.	50 per cent ad valorem.
		Terry-woven fabrics, composed wholly or in chief value of cotton, and manufactures, in any form, made or cut from terry-woven fabrics.	40 per cent ad valorem.

COURT AND TREASURY DECISIONS.

The provision in paragraph 350 of the act of 1890 for "plushes, velvets, velveteens, corduroys, and all pile fabrics composed of cotton or other vegetable fiber" was construed to apply only to goods in

the piece and not to include velveteen dress facings, which were classified as manufactures of cotton under paragraph 355 of that act (Kursheedt Manufacturing Co. *v.* United States, 54 Fed., 159, of 1893). It was not until 1897 that a provision was made for articles made or cut from plushes, velvets, velveteens, corduroys, and other pile fabrics of cotton or other vegetable fiber in connection with those materials. In the act of that year (par. 315) the manufactured articles were made subject to the same rates of duty as the pile fabric materials and in addition thereto 10 per cent ad valorem. Pile fabrics in chief value of flax were held to be excluded from the provisions in that paragraph for pile fabrics (Stern *v.* United States, 98 Fed., 417, of 1899). Trimmings cut out of cotton velvet fabric in various open and scroll work designs and colors were held to come within that provision for cotton pile fabrics and not to be dutiable as cotton trimmings (Horstmann *v.* United States, 121 Fed., 147, of 1903). A pile fabric commercially known as velvet cord, ribbed velvet, or corded velvet was held not to be corduroy composed of cotton or other vegetable fiber within paragraph 315 of the act of 1897 (Stewart, etc., *v.* United States, 113 Fed., 928, of 1902). No rule was declared to exist in trade or commerce regarding fabrics having a pile of 3.5 millimeters or less in length as velvets, and those over 3.5 millimeters as plush (United States *v.* Silberstein, 153 Fed., 965, of 1907.)

The provision in paragraph 325 of the act of 1909 for "plushes, velvets, velveteens, corduroys, and all pile fabrics, cut or uncut, whether or not the pile covers the entire surface," was declared broad enough to include any pile fabric as commonly understood. The phrase "cut or uncut" was interpreted not to restrict the meaning, but merely to make the meaning clear. (Knauth *v.* United States, 6 Ct. Cust. Appls., 128, of 1915).

The provision for velvets composed of cotton or other vegetable fiber was declared more specific than the provision in paragraph 321 for cloth composed of cotton or other vegetable fiber and silk, and was held to include velvet composed in chief value of cotton with silk back. (Abstract 36784, T. D. 34871, of 1914.)

Cotton terry cloth has been variously classified. Under the act of 1890 it was held to come within the provision for manufactures of cotton rather than as countable cotton cloth or as pile fabrics. (G. A. 2310, T. D. 14499, of 1893.) It was held dutiable as countable cotton cloth under the act of 1897 (G. A. 5838, T. D. 25746, of 1904). It was held dutiable as pile fabrics uncut under the act of 1909 (G. A. 7572, T. D. 34545, of 1914), and as pile fabrics under the act of 1913 (T. D. 34287, of 1914).

Pile fabrics composed in chief value of cotton chenille were held to be more specifically provided for as pile fabrics than as articles of which cotton chenille is the component material of chief value (Abstract 43268, of 1919).

Loop crêpe was classified as cotton cloth (Abstracts 38432, of 1915, and 39410, of 1916).

TAPESTRIES AND OTHER JACQUARD FIGURED UPHOLSTERY GOODS.

[Paragraph 258, act of 1913; paragraph 909, act of 1922.]

SUMMARY.

The domestic industry normally produces most of the Jacquard woven upholstery goods, such as tapestry, brocatelle, pocket cloths, armures, damasks, and brocades, that are required for domestic consumption. Imports are mainly on the ground of quality or design.

Judicial interpretation of the phrase "Jacquard figured upholstery goods" in paragraph 258 of the act of 1913, was to make chief use rather than eo nomine specification the controlling rule of classification, and, therefore, to admit under paragraph 258 not only loom-woven madras muslin but also nets, nettings, and laces, if Jacquard figured and intended for use as curtains or other decoration of apartments, although such goods were made on net, Levers lace, or other special machines. The record import of $3,259,906 in the calendar year 1921 was due mainly to the inclusion of such lightweight lace-like fabrics under the import classification of Jacquard figured upholstery goods. To remedy this situation and to make clear the intent of Congress there was substituted in the act of 1922 (par. 909) the more restrictive wording "Jacquard woven upholstery cloths."

GENERAL INFORMATION.

DESCRIPTION.

Tapestries are yarn-dyed figured fabrics made with two or more sets of warp yarns and two or more sets of filling yarns, and the machine-made goods are always woven with a Jacquard. The designs are elaborate and require a larger number of cards than are necessary for most Jacquard fabrics. In weaving these double-texture cloths of intricate designs it is necessary to employ a weaver to each loom and the rate of production is very slow. There are different qualities, but as a rule labor forms a larger proportion of the total cost of manufacture than with the general run of fancy goods.

Tapestries are upholstery fabrics. They are used for covering not only furniture and walls but also seats in inclosed automobiles and in railway coaches. As panels they are hung for wall decoration, as pictures are used. They are also used for making curtains, portières, pillow tops, table covers and scarfs, or as borders for trimming such articles. They are also extensively used for appliqué on plain fabrics.

Tapestries rarely weigh less than 6 ounces per square yard, the majority being much heavier.

Imports are largely in widths of about 50 inches, in pieces containing a continuous picture or tapestry design; there is also a fair proportion imported in short lengths for use as wall or screen panels, and many of these are made by hand or on hand looms. When made by hand, according to the original method, there is employed a vertical warp and into this the short lengths of filling yarns of the various colors required to form the design are inserted by hand. Pre-war imports of tapestry were mainly from France, particularly from the Roubaix-Tourcoing section, and Belgium. This tapestry

manufacture was stopped by the invasion of the Germans in September, 1914, and such tapestry as was received in America after that date was from stock in the hands of Paris and London jobbers, supplemented by a small amount of English-made tapestries.

Other Jacquard figured upholstery cloths of a somewhat similar nature to tapestries, in that two or more sets of warp yarns and two or more sets of filling yarns are employed to produce a cloth of double texture, include such goods as brocatelle and "pocket cloths." Brocatelle is defined [9] as "A double cloth fabric, with two warps and two fillings, a face warp and weft, and a back warp and weft. These warps and fillings, however, interweave with one another, thereby binding together the two sets of warp and filling threads, with this peculiarity, that the face warp threads do not show on the back of the fabric nor does the back filling show on the face of the fabric, whereas, on the contrary, the face filling shows on the back and the back warp threads show on the face." The term "pocket cloths," as used in the Philadelphia upholstery industry, refers to another type of double cloth where two or more sets of warp and of filling yarns are used to produce two cloths, one above the other, which are interwoven only at certain Jacquard figured points; the effect is that of a fancy quilted fabric.

"Tapestry" is a term that applies to a fairly definite class of fabrics but this is not true as to the term "other Jacquard figured upholstery goods" which was bracketed therewith in the tariff acts of 1909 and 1913. "Upholstery goods" is a general term that has no definite, uniform, and general meaning throughout the trade, although some dealers differentiate between upholstery goods used for covering furniture, and drapery goods such as curtains. In Bing *v.* United States (3 Ct. Cust. Appls., 115; T. D. 32365, of 1912) the court cited with approval the definition of "upholstery goods" given in the Century Dictionary and the Standard Dictionary in terms broad enough to include all the interior textile decorations of an apartment.[10] The lexicographic definition thus quoted in 1912 became the legal definition because the courts found such great diversity in testimony given by business men as to prove that the term is a very loose one commercially.

Under the act of 1909 no attempt was made to include Jacquard figured laces, nettings, trimmings, braids, and ornaments made of cotton, even though they weighed in some instances over 6 ounces per square yard and were used for curtains, under the new provision for Jacquard figured upholstery goods and they remained dutiable as laces, nettings, etc., at a higher rate. (See T. D. 37465, G. A. 8119, as to testimony to this effect offered by the Government.)

The omission in the act of 1913 (par. 258) of the words "weighing over 6 ounces per square yard" was construed by the Court of Customs Appeals to enlarge the meaning of the term "upholstery goods" to include goods of a lighter and less substantial nature than woven piece goods and articles used as furniture or wall coverings. All Jacquard figured textile fabrics or articles used as interior decorations or fittings of apartments were therefore held to be

[9] See "A Cotton Fabrics Glossary," by Bennett, p. 528.

[10] The Century Dictionary defines *upholstery* as furniture covered with textile material, and hangings, curtains, and the like. A general term for all such interior decorations and fittings as are made with textiles.
The Standard Dictionary defines *upholstery* as goods or materials used in upholstering; textile decorations of an apartment.

"Jacquard figured upholstery goods," including not only light curtain goods such as the clipped "madras muslin" woven on a loom, but curtain goods not made on a loom at all, such as Jacquard figured nets and laces, also doilies, bureau scarfs, tidies, and other articles made by sewing together hand-made laces, machine-made laces, and embroideries. The effect of this judicial interpretation was to make chief use rather than eo nomine specification the controlling rule of classification and many of the higher and more advanced goods which were assumed to be dutiable in the act of 1913, under paragraph 358, at 60 per cent ad valorem, were later brought in under paragraph 258, at 35 per cent ad valorem, although those made without the use of the Jacquard, such as plain nets, remained dutiable at the higher rate.

DOMESTIC PRODUCTION.

Materials.—The main material used in the domestic upholstery mills is dyed cotton yarn. This is used in counts from 4s to 80s, single and ply. The great majority of the cotton yarns used is in coarse and medium counts under 40s. Most of the upholstery mills also use more or less yarns of other material, particularly wool, spun silk, and artificial silk.

Methods of production.—The essential point of demarcation between upholstery mills and mills producing Jacquard fabrics for use as wearing apparel is in the greater size and more elaborate character of the patterns, involving the use of a much larger number of Jacquard cards. The first cost of producing and placing on the loom a tapestry or similar Jacquard upholstery design is usually much greater than that of Jacquard designs for dress goods and the cost of the fabric is much enhanced thereby, particularly as many of these fabrics are sold in limited quantities of any one pattern.

Organization.—The upholstery mills as a rule buy all yarns required and confine themselves to yarn dyeing, weaving, and finishing.

Geographical distribution.—The manufacture of cotton tapestries, brocatelles, pocket cloths, armures, damasks, brocades, and similar goods of the elaborate design and substantial texture used for covering furniture and walls, usually known as Jacquard figured upholstery goods, is mainly concentrated in Philadelphia. This section of the industry, however, appears to have been stationary for some time so far as regards quantity of output, although the value of the output has been steadily increasing. There are a few mills in Pennsylvania outside of Philadelphia, and the number in New Jersey and other States is increasing. In 1899 Pennsylvania produced over 94 per cent of the cotton tapestry yardage of the country, but in 1914 its proportion was slightly less than 80 per cent, and in 1919 it had dropped to less than 42 per cent. The tapestries produced in other States, however, are lighter and less valuable per yard, so that in 1919 Pennsylvania accounted for more than three-fourths of the total value.

Domestic production.—Domestic production of "cotton tapestries" was practically stationary in the period from 1899, when it amounted to 10,166,538 square yards, valued at $4,158,600, to 1914, when it amounted to 10,137,710 square yards, valued at $5,411,592. In the next five years, however, the production more than doubled, amounting to 21,705,586 square yards, valued at $17,295,608, in

1919. The census figures are for "cotton tapestry" only, and the production of other heavy Jacquard woven upholstery fabrics, such as brocatelle, pocket cloths, armures, damasks, and brocades, is not recorded separately; the same is true of light Jacquard woven upholstery fabrics such as madras muslin. Inasmuch as the Census records separately only a portion of the Jacquard woven upholstery cloths, it is not possible to make any exact contrast as to the proportion that imports bear to the total domestic consumption.

FOREIGN PRODUCTION.

The principal foreign producing nations are France and Belgium, with England and Germany ranking next.

IMPORTS.

Beginning in 1915, decisions of the Court of Customs Appeals classified as dutiable under paragraph 258 an increasing range of goods, particularly Jacquard figured nets, nettings, and laces, for curtain use, which were previously dutiable under paragraph 358. Refunds of duties were made in those cases, but customs officials continued to assess the 60 per cent rate pending final determination of the dutiable classification. This litigation was in the main ended in favor of the 35-per cent rate and the figures of imports for recent years, particularly 1920 and 1921, include large quantities of Jacquard figured nets, nettings, and laces used for drapery or upholstery purposes. These fabrics were not so included under the 1909 wording and the proportion so included in the earlier years of the 1913 act is not clear, but the continual enlargement of the meaning of the term "Jacquard figured upholstery goods" obscures any interpretation of the actual effect of the lowering of the rate of duty from 50 per cent in 1909 to 35 per cent in 1913.

Imports of "Tapestries and other Jacquard woven upholstery goods" were valued at $363,639 in the fiscal year 1911, the first complete year under the act of 1909, and at $3,259,906 in the calendar year 1921, the last complete year under the act of 1913. As shown above, however, the articles included under this heading in the two periods are not the same and the figures are not comparable. As far as Jacquard woven upholstery cloths (the more restrictive classification adopted in the act of 1922) are concerned, there has probably been little, if any, increase in imports during the past decade.

TARIFF HISTORY.

Tapestry panels and other goods cut or manufactured from tapestry were classified as manufactures of cotton not otherwise provided for until 1903, when they were held to be dutiable as countable cottons. (United States *v.* Bernhard, 150 Fed. 375; T. D. 24352, G. A. 5319.) This decision led to the domestic manufacturers of tapestry presenting a brief to Congress and requesting specific mention of their goods in the act of 1909. In accordance therewith there was inserted in the act of 1909, in paragraph 326, a section reading:

* * * Tapestries, and other Jacquard figured upholstery goods, weighing over 6 ounces per square yard, composed wholly or in chief value of cotton or other vegetable fiber; any of the foregoing in the piece or otherwise, 50 per centum ad valorem.

This provision was retained in paragraph 258 of the act of 1913, with the exception that the modifying phrase "weighing over 6 ounces per square yard" was omitted, and the rate of duty was reduced to 35 per cent ad valorem.

In the act of 1922 the wording was changed to "Tapestries and other Jacquard woven upholstery cloths," the intent of the substitution of "woven" in lieu of "figured," and of "cloths" in lieu of "goods" being to prevent the possibility of net or lace of any kind or for any use being included hereunder. In addition to Jacquard woven upholstery cloths, however, paragraph 909 of the act of 1922 includes at the same rate of duty "Jacquard woven blankets and Jacquard woven napped cloths."

[1] Not recorded.
[2] Covers period Aug. 6, 1909, to June 30, 1910, inclusive.
[3] Includes manufactures of chenille which, however, constituted but a small portion of the total imports shown.
[4] Average for 10.9 years.
[5] Plus 7 cents a pound if containing cotton of 1⅛-inch staple or longer. (Emergency tariff act of May 27, 1921.)
[6] Includes 241,600 pounds, valued at $561,837, paying additional duty of $16,912, because of the 7 cents a pound surtax levied by the emergency tariff act.
[7] Includes 178,063 pounds, valued at $584,417, paying additional duty of $12,464, because of the 7 cents a pound surtax levied by the emergency tariff act.

Tapestries and other Jacquard figured upholstery goods—Rates of duty.

Act of—	Par.	Tariff classification or description.	Rate of duty.
1909	326	* * * tapestries, and other Jacquard figured upholstery goods, weighing over 6 ounces per square yard, composed wholly or in chief value of cotton or other vegetable fiber; any of the foregoing, in the piece or otherwise.	50 per cent ad valorem.
1913	258	* * * tapestries, and other Jacquard figured upholstery goods, composed wholly or in chief value of cotton or other vegetable fiber; any of the foregoing, in the piece or otherwise.	35 per cent ad valorem.
1922	909	Tapestries, and other Jacquard woven upholstery cloths, Jacquard woven blankets and Jacquard woven napped cloths, all the foregoing, in the piece or otherwise, composed wholly or in chief value of cotton or other vegetable fiber.	45 per cent ad valorem.

Court and Treasury Decisions.

In the act of 1909 (par. 326) tapestries and other Jacquard figured upholstery goods were specifically provided for, with a limitation, however, to those "weighing over 6 ounces to the square yard." While this act was in force there were imported Jacquard figured cotton panels of various sizes intended for use in screens. The importers contended that the panels did not serve utilitarian purposes, such as curtains and furniture coverings, and therefore were not properly upholstery goods. The Court of Customs Appeals, however, took the view that the term "upholstery goods" in its ordinary meaning, which did not differ from any proved commercial designation, included the merchandise in issue because they were textile decorations of apartments (Bing *v.* United States, 3 Ct. Cust. Appls., 115, of 1912). The definition in that case of the term "upholstery goods," as used in paragraph 326 of the act of 1909, was subsequently declared "broad enough to include all the interior textile decorations and fittings of apartments" (United States *v.* Mills, 8 Ct. Cust. Appls., 422, 425, of 1918).

In the act of 1913 (par. 258), the words "weighing over 6 ounces per square yard" were omitted. This omission was construed by the Court of Customs Appeals to enlarge the meaning of the term "upholstery goods" to include goods of a less substantial character and weight than those weighing more than 6 ounces to the square yard and to comprehend nettings chiefly used for curtains (Carter *v.* United States, 6 Ct. Cust. Appls., 253, of 1915).

The Carter case was followed in United States *v.* Mills, 7 Ct. Cust. Appls., 388, of 1917, and 8 Ct. Cust. Appls., 422, of 1918, and in other cases. A commercial meaning different from common usage, excluding nets and nettings from the term "upholstery goods," was declared by the court not to be established. The effect of these decisions was to make chief use rather than eo nomine specification the controlling rule of classification and to subject Jacquard figured upholstery goods to a lower rate of duty than plain nets and nettings. The court took into consideration the fact that Congress was aware of the decision in Bing *v.* United States, supra, and it made no change in the paragraph except to omit the limitation that only such upholstery goods as weighed over 6 ounces per square yard should be dutiable thereunder (8 Ct. Cust. Appls., 426).

Two decisions of the Board of General Appraisers made in 1920 indicate the extent to which the rule of chief use was applied

to Jacquard figured upholstery goods. After following the decisions of the Court of Customs Appeals in classifying as upholstery goods Jacquard figured cotton lace, the chief use of which is for the decoration of bureau scarfs, table doilies, and similar articles used on household furniture (G. A. 8328, T. D. 38317, of Mar. 9, 1920), the board held that the finished products—doilies, bureau scarfs, tidies, and similar articles made by sewing together handmade laces, embroideries, and Jacquard figured machine-made laces—came within the provisions for Jacquard figured upholstery goods in paragraph 258 (G. A. 8359, T. D. 38464, of June 30, 1920). In this decision the board said:

> We were unable to agree with the contention of the Government in that case (G. A. 8328, T. D. 38317, supra) that a distinction should be made somewhere between such things, on the one hand, as curtains, wall hangings, and permanent furniture coverings, and, on the other hand, the decorative textile articles which are found in household apartments as ornaments for some article therein.

The board gave as a reason:

> It is well known, as counsel for the importers state in their brief, that in interior decorations of apartments it is customary to treat such articles as bureau scarfs, doilies, bed sets, pillow shams, etc., as a part of the decorative scheme, and that they harmonize with and are frequently made out of the same materials as the draperies, wall coverings, and furniture coverings.

The board furthermore disagreed with the Government counsel in the contention that the provisions for Jacquard figured upholstery goods was intended to cover only such upholstery goods as in their imported condition may be said to be the product of a machine with a Jacquard attachment, and that it was not intended to cover upholstery goods made in part of Jacquard figured goods and in part of other materials. The reason for the dissent as expressed in the board's opinion is as follows:

> There might be some force in the contention of the Government if the law provided for upholstery goods made on a machine with a Jacquard attachment. The provision, however, is for Jacquard figured upholstery goods, and we think the requirements of the statute are met when it is shown, as it is in this case, that the articles are Jacquard figured and that they are upholstery goods. This provision has been the subject of much litigation, and the term "upholstery goods," as we have said, has been defined as including all the interior textile decorations and fittings of apartments, and it has been held that the test of classification under the provision is the use to which the goods are applied. The provision has not been limited to materials for making "interior textile decorations and fittings of apartments," but has been held to include complete articles, such as curtains, panels to be used as panels of screens or to be hung upon the walls, table covers, etc.

Madras muslin curtains in the piece, madras muslin curtains, and madras muslin curtains scalloped, Jacquard figured, were also in issue and were held to come within the provision for Jacquard figured upholstery goods in paragraph 258 (United States *v.* Snow's United States Sample Express Co., 6 Ct. Cust. Appls., 477, of 1916, same *v.* same, 8 Ct. Cust. Appls., 351, of 1918). Judge Smith dissented as to the scalloped goods. The principles of construction applicable to these goods are stated as follows in the head notes of the Snow's Express Co. case in 8 Court of Customs Appeals, 351:

> 1. Construction, paragraph 358, tariff act of 1913.
>
> The provision of paragraph 358, tariff act of 1913, "all articles or fabrics * * * scalloped by hand or machinery * * * by whatever name known" is equivalent to an enumeration of every scalloped article by its name, and amounts to an eo nomine designation of scalloped madras muslin curtains.

2. Construction, paragraph 258, tariff act of 1913.

Regardless of relative specificity of the terms employed, the intention of Congress, in the enactment of paragraph 258, tariff act of 1913, was to make the language "curtains * * * and other Jacquard figured upholstery goods, composed wholly or in chief value of cotton or other vegetable fiber; any of the foregoing in the piece or otherwise," inclusive of all goods falling therewithin and to exclude therefrom all other provisions of the act.

3. Construction—designations eo nomine and by use.

Where Congress has provided for an article eo nomine in one paragraph of a tariff act, and in another paragraph of the same act employs language comprehensive of the other designation, and rates it for duty according to use or when used for a certain purpose, there is manifested a strong evidence of an intention upon the part of Congress to make that use controlling and to make the designation by use operate as an exception to the eo nomine designation.

4. Scalloped Jacquard figured madras muslin curtains in the piece and otherwise and materials therefor.

Scalloped Jacquard figured madras muslin curtains in the piece and otherwise and materials therefor are dutiable under paragraph 258, tariff act of 1913 ("curtains * * * and other Jacquard figured upholstery goods, composed wholly or in chief value of cotton or other vegetable fiber; any of the foregoing in the piece or otherwise") and not under paragraph 358 ("all articles or fabrics * * * scalloped by hand or machinery * * * by whatever name known").

COTTON TABLE DAMASK, AND MANUFACTURES THEREOF.

[Paragraph 263, act of 1913; paragraph 911, act of 1922.]

SUMMARY.

The domestic production of cotton table damask has grown until it now supplies the bulk of the domestic demand and in addition furnishes considerable quantities for export to foreign countries.

The record value of imports of cotton table damask and manufactures thereof was reached in the fiscal year 1920 with $1,662,643, of which less than half consisted of cotton table damask in the piece. The highest pre-war value of imports was $759,491 in 1904; taking into consideration the subsequent rise in prices it is probable that there were more square yards of cotton table damask imported in 1904 than in 1920.

While imports are competitive, they are sold mostly in conjunction with imported linen table damask. Post-war increases in the total quantity of cotton table damask in the piece and manufactures thereof are due most largely to an increase in the latter, and though these are also competitive, they may be considered more supplementary, as they take the place of the linen damasks which have become scarce and dear.

GENERAL INFORMATION.

DESCRIPTION.

Damask is a single-structure fabric, Jacquard woven,[11] with the same type of weave used for both figure and ground, and distinguished by the fact that the design shows up on the smooth surface without the necessity of any contrast in color. The weave employed is a sateen twill (mainly 5 or 8 harness), the warp and filling being interchanged so as to show solid warp-sateen figures on a filling-sateen ground, or

[11] A domestic manufacturer of cotton table damask comments on this as follows: "Your definition is correct. Some tablecloths are woven on the dobby, but these are not damask, strictly speaking. The same statement applies to tablecloths woven with a plain weave, as damask is always made with a sateen twill."

vice versa. The threads in the figure lie at right angles to those in the ground, with the result that the light falling on the smooth surface of the cloth is refracted and the pattern made apparent. The clearness of the figure may be intensified by the use of warp and filling yarns that differ in material, twist, or luster; for instance, by the use of cotton warp and linen filling or a mercerized cotton warp and a plain cotton filling.

Damasks are made of silk, linen, cotton, wool, or other materials, and used for dress goods, upholstery, and other purposes. Table damasks are mainly of linen, of cotton, or of a union of the two. The soft natural luster of fully bleached flax, with its highly reflective power, makes it the favorite material for bleached damasks, and its peculiar qualities are intensified by beetling and calendering. Cotton table damask is an imitation of the more costly linen table damask and is very similar in width, weight, and design; it can also be made and usually is made to closely resemble it by subjection to mercerizing and other finishing treatments, but while the appearance of linen improves with domestic washing, that of cotton deteriorates. Some cotton table damask is woven in colors, usually Turkey red, blue, or tan, with white, but the majority is all white.

Manufactures of cotton table damask are largely tablecloths, table runners, napkins, and doilies. These may be cut from the ordinary cotton table damask in the piece and hemmed, but especially in the case of tablecloths and napkins, are more often cut and packed unhemmed in individual wrappings. These usually contain one tablecloth to the package of one dozen napkins, one piece, to the package. These tablecloths and napkins are cut from specially woven fabrics specially designed for cutting into specific lengths. A typical example is an 8 by 8-foot, or an 8 by 10-foot cloth, with a deep border design around the four sides. The package of napkins to match may be a piece 24 to 36 inches in width and long enough to cut into a dozen square napkins whose design is based on that of the cloth. The best linen damask is sold in sets of one dozen napkins and one cloth, but the bulk are of standard designs and are sold either separately or in sets. This is the case with cotton table damask.

DOMESTIC PRODUCTION.

The census did not record the production of cotton table damask prior to 1919, in which year it amounted to 27,499,294 square yards (10,543,966 pounds), valued at $9,544,478.

Materials.—Cotton table damasks are made of coarse to medium yarns, between 16s and 30s singles, using ordinary upland cotton. One manufacturer is now experimenting with ply yarns in order to produce a fabric that will compete with the best grade of imports.

Equipment.—The Jacquard loom used in American damask mills is of domestic manufacture and is similar to those used in weaving other Jacquard fabrics of the same class. Narrow looms can be used for such goods as napkins, but wide looms are necessary for tablecloths. The damask fabrics for tablecloths run from 54 to 72 inches in width, with the 58-inch width predominating.

Organization.—Most of the mills are self-contained, weaving damask from yarns spun in the same establishment. Some mills do their own finishing, but the majority of these goods are finished in outside plants which make a specialty of this line. One finisher, who handles the output of several plants, has perfected a finish in which viscose is used to impart to the cotton damask a linenlike gloss that is very durable. Most cotton table damasks are mercerized.

Geographical distribution.—The production of cotton table damask is not confined to any particular locality. The Official American Textile Directory, 1922, lists 43 mills, distributed through 12 States, making cotton damask. The largest producers are apparently North Carolina, Massachusetts, and Maine.

Domestic exports.—The domestic industry has built up a substantial export trade in cotton table damask. There are no exact statistics as to the amount of this trade, but Canada records imports from the United States valued at $132,259 in 1919 and $80,021 in 1922, fiscal years ended March 31. The shipments to Canada are only an indication, as it is known that there are also large shipments of American-made damask to Cuba, Argentina, Chile, and various other countries.

IMPORTS.

During the 30 years, 1891–1920, imports of cotton table damask, including manufactures of, averaged $463,875, ranging from a low of $153,551 in 1897 to a high of $1,662,643 in 1920. The highest pre-war value of imports was $759,491 in 1904; taking into consideration the fact that the unit values have considerably more than doubled, it is probable that the quantity of imports in 1904 was larger than in any subsequent year. The duties collected during these 30 years have averaged $156,879 annually, ranging from a low of $53,743 in 1897 to a high of $415,661 in 1920. Imports in the calendar year 1921 were valued at $1,097,929, on which the duty amounted to $276,875.

Manufactures of cotton table damask were not recorded separately from cotton table damask in the piece prior to the fiscal year 1910. The figures since that year indicate that prior to 1917 the importation of articles made of cotton table damask was negligible and that imports of cotton table damask consisted almost entirely of goods in the piece. Starting with 1917, imports of manufactures of cotton table damask increased until in the fiscal year 1919 they exceeded in value the imports of cotton table damask in the piece; this condition has held true in succeeding years. It will be noticed that the imports of cotton table damask as a whole were smaller in 1916 than in any year since 1901. Flax had by that time become so scarce and costly that the manufacturers of linen damask at Dunfermline and other foreign centers were forced to take up the production of all-cotton damasks as well as of union (linen and cotton) damasks in order to keep their plants going.

TARIFF HISTORY.

"Cotton damask" was first provided for in the act of 1883; this applied only to cotton damask in the piece and it was held (T. D. 8600 of 1887) that completed articles, such as table covers, were dutiable as manufactures of cotton. In the acts of 1890 (par. 355) and 1894 (par 264) this was changed to read "cotton damask, in the piece or otherwise." The words "in the piece or otherwise" were omitted in the act of 1897 (par. 321) and the word "table" inserted, making the provision read "cotton table damask." In the act of 1909 (par. 331) and in the act of 1913 (par. 263) the provision was for "cotton table damask, and manufactures of cotton table damask, or of which cotton table damask is the component material of chief value, not specially provided for in this section." In the act of 1922 (par. 911) the wording was changed to read "table damask composed wholly or in chief value of cotton, and manufactures, in any form, composed wholly or in chief value of such damask."

COMPETITIVE CONDITIONS.

The imported fabric has, in the opinion of most importers, a finish that resembles true linen more closely than does the usual domestic finish, and the fact that much of the increased shipments since 1916 are produced by linen manufacturers, designed and packed the same as linen, and labeled as imported, adds to their salability. Imports of cotton table damask compete with the domestic manufacture, but imports during the last few years have been to a certain extent supplementary in that they took the place of the former imports of linen table damask. The substitution of cotton imports for linen imports has been particularly noticeable in the increased shipments of the finished articles, such as tablecloths, napkins, and doilies, and to a less extent in that of goods in the piece. The domestic manufacturer controls the great bulk of the normal demand for cotton table damask, and unless linen prices again come within reach of the average consumer the high-speed, bulk-production methods of the American manufacturer will eventually allow him to take the greater part of the new trade on price as he did the old.

FOREWORD.

The tables here printed were referred to on page 41 of Tariff Information Survey I-3 entitled "Countable Cotton Cloths." They were originally intended for inclusion therein but were omitted in order to expedite the printing of that report for the use of the Committee on Ways and Means. In the original manuscript form these tables were used by that committee and also by the Finance Committee in their preparation of the tariff law. They have since been rounded out by the insertion of the rates of duty applicable under the act of 1922 and are printed in response to requests by the trade.

In the preparation of this report the Tariff Commission had the services of W. A. Graham Clark, special expert, and of others.

ONE HUNDRED IMPORTED COTTON CLOTHS.

There are shown herewith physical, price, and tariff data relating to 100 foreign cotton cloths selected, in 1920, as typical of imports in this line. In making the selections the Tariff Commission had the assistance of importers and customs examiners. Photographs of these cloths are appended.

Table 1 shows physical and price data. The physical data include the so-called "cloth particulars," that is, the width in inches, the weight (stated in linear yards per pound, in square yards per pound, and in ounces per square yard), the ends and picks per square inch, and the yarn number and ply of both warp and filling. There is also listed the total single threads per square inch; in cloths composed of single yarns only, the total is the sum of the ends and picks, but in cloths containing ply yarns these are separated into singles and the count is taken of the total singles. There is further shown the official average yarn number, obtained by considering the length of the yarn to be equal to the distance covered by it in the cloth in the condition as imported, except that all clipped threads are considered as continuous. The width in inches is multiplied by the linear yards per pound and by the total single threads per square inch, and the result divided by 840. This official average yarn number, which has been in continuous use for tariff purposes since October 3, 1913, is always somewhat coarser than the actual average yarn number by reason of its disregarding the amount (difficult of precise ascertainment) by which the actual length of yarn used exceeds the surface length of the cloth produced.[1] The physical data presented also show the finish given to the yarn or to the cloth; where no finish is stated after the yarn it was used in the grey (unbleached) state.

The 100 cotton cloths selected include 90 known to the customs as "countable cotton cloths," because the threads must be counted to ascertain the progressive rate of duty to be applied, and 10 special cloths, provided for eo nomine, dutiable without respect to the threads per square inch or to the average yarn number based thereon. The 90 countable cotton cloths are made up of 41 plain cloths (plain-woven, twill, or sateen fabrics) woven with grey yarns; 18 plain cloths in which dyed yarns are used; 16 cloths requiring the use of the dobby or the Jacquard attachment; 2 made with leno doups; 2 containing novelty yarns; 2 with effects produced by clipping floating threads; and 9 made on swivel or lappet looms. The 10 cotton cloths provided for eo nomine include coated cloths, filled cloths, waterproof cloths, cotton table damask, Jacquard figured upholstery cloths (light and

[1] The fact that the length of yarn used is more than the length of the cloth produced is due, of course, to the necessity of the two sets of interweaving yarns, warp and filling, bending out of their course in order to pass around each other.

heavy), and pile fabrics. The 100 samples selected, therefore, cover practically the full range of imported cotton cloths, both countable and eo nomine, and afford not only a perspective of the import trade in this line but also a basis for tariff contrasts.

The price columns in Table 1 show, for each cloth, prices taken from the invoices nearest to October 1, 1913, and May 1, 1920. The first may be taken as typical of normal pre-war prices, whereas the latter are peak prices. It is hardly probable that prices will recede to those obtaining before the war, or that they will in the immediate future exceed those attained at the height of the boom in the spring of 1920. These two price levels were selected as the limits between which prices will probably fluctuate under the act of 1922 and therefore as well adapted to bring out the fluctuations in the relative duty levels under different acts. Owing to the differences in methods of adjustment of duties under the last three tariff acts, which, when measured on any common basis such as the ratio of the duty to the invoice value, cause the relative heights of the duty to vary irregularly with price changes, a fairer contrast can be obtained by using two price limits than by taking the prices of any particular day in 1923 or other year. Prices on cotton cloth invoices are usually stated on the basis of the linear yard; these are shown in Table 1 with the foreign currency converted to American currency at the ruling rates of exchange; there are also given the equivalent prices per square yard and per pound.

Table 2 brings out the relative height of tariff duties, stated in terms of cents per pound and also in ad valorem terms, under the acts of 1909, 1913, and 1922, based first on the normal price level of October 1, 1913, and second on the peak price level of May 1, 1920.

Under the act of 1922, countable cotton cloths are dutiable under progressive specific rates of duty, with progressive ad valorem minimums, and with a flat maximum of 45 per cent ad valorem. A study of the rates of the act of 1922 given in Table 2 shows that if the pre-war (1913) prices were in force now (1923), 28 of the 90 countable cloths would be dutiable under the specific rates, 38 under the minimum ad valorem rates, and 24 at the maximum of 45 per cent ad valorem. If the peak prices of May 1, 1920, were in force now, none of the 90 cloths would be dutiable under the specific rates, 82 would be dutiable under the minimum ad valorem rates, and 8 at the maximum of 45 per cent ad valorem. Prices in the spring of 1923 were approximately halfway between the 1913 and 1920 quotations, and less than a fourth of the imports of countable cotton cloths were dutiable under the specific rates of duty, the great bulk being dutiable under the progressive minimum ad valorem rates.

As shown by Table 2, the average rates of duty, on the 100 selected cloths, under the tariff acts of 1909, 1913, and 1922, vary according to the price level used.

Contrast of equivalent ad valorem rates of duty.

Tariff act.	Average duties, using 1913 prices.			Average duties, using 1920 prices.		
	90 countable cloths.	10 eo nomine cloths.	Total, 100 cloths.	90 countable cloths.	10 eo nomine cloths.	Total, 100 cloths.
	Per cent.	*Per cent.*	*Per cent.*	*Per cent.*	*Per cent.*	*Per cent.*
1909	44.82	53.22	45.76	37.26	35.13	37.05
1913	21.92	30.50	22.78	21.92	30.50	22.78
1922	33.31	49.23	38.23	29.34	36.40	32.98

Analysis of the above, so far as the 90 countable cotton cloths are concerned, shows that the rates of the act of 1922 are approximately halfway between the rates of the acts of 1913 and 1909. If based on 1913 prices, the rates under the present act are 51.5 per cent higher than those of the act of 1913 and 25.9 per cent lower than those of the act of 1909; if based on 1920 peak prices, the rates under the present act are 33.9 per cent higher than those of the act of 1913 and 21.3 per cent lower than those of the act of 1909. In regard to cotton cloths provided for eo nomine, if based on 1913 prices, the rates under the present act are 61.4 per cent higher than those of the act of 1913 and 7.5 per cent lower than those of the act of 1909; if based on 1920 peak prices, the rates under the present act are 19.3 per cent higher than those of the act of 1913 and 3.6 per cent higher than those of the act of 1909. For the 100 cotton cloths, including both countable and eo nomine, it is seen that the average rates of duty under the acts of 1913, 1922, and 1909 bear the relation of 100, 168, and 200 if based on the low price level, and the relation of 100, 145, and 163 if based on the high price level.

These averages, taken from Table 2, are simple arithmetical averages; as the relative quantities of the various cloths imported fluctuate from year to year it is not possible to weight them to complete the contrasts on the price levels taken. Import statistics, however, show that the rate of duty on countable cotton cloths imported during the operation of the act of 1909 averaged 42.30 per cent ad valorem, as against 21.42 per cent ad valorem for similar imports during the operation of the act of 1913. The rate of duty on all cotton cloths, countable and eo nomine, imported under the act of 1909 averaged 44.24 per cent ad valorem, as against 23.46 per cent ad valorem for similar inclusive imports under the act of 1913. Taking into consideration the fluctuating price levels during the years of operation of these acts, and the fact that the relative duty levels vary irregularly, not uniformly, according to price level variations, the average rates of duty during the entire periods of the acts of 1909 and 1913 are remarkably close to the average of the rates on the 100 cloths based on two price levels shown in Table 2. These figures tend to prove that the 100 cotton cloths selected are fairly representative of the range of imports in this line and that the contrast of tariff rates given in Table 2 may be taken as a closely approximate indication of the relative height of the cotton cloth duties that will obtain under the act of 1922 as compared with those under the acts of 1909 and 1913.

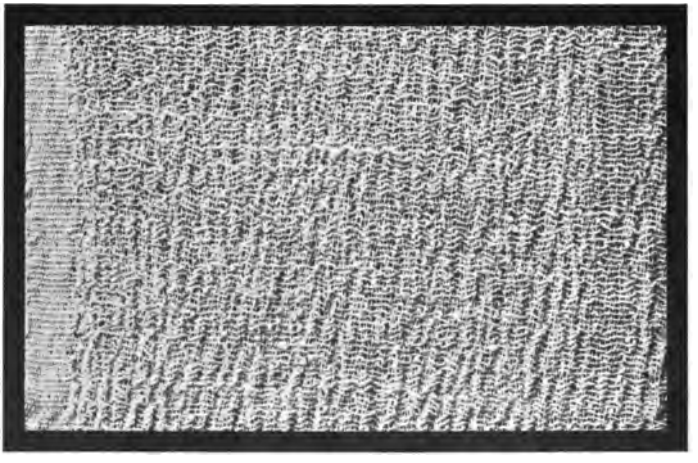
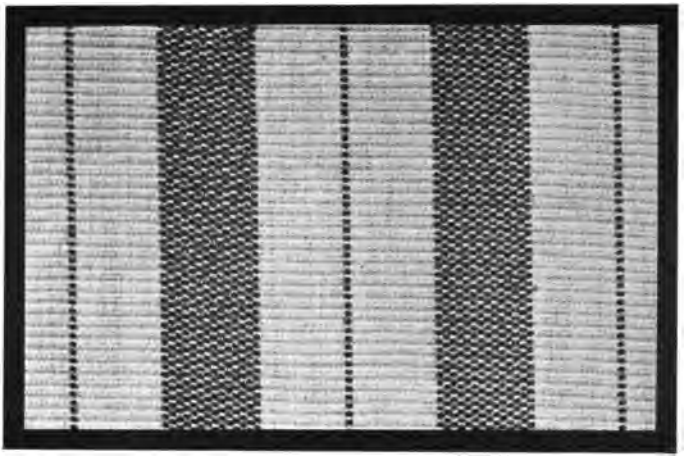
SAMPLE NO. 3.—MOLESKIN.

Filling sateen (6-harness). Finished width, 30 inches.
67 ends and 284 picks per square inch, finished.
Warp yarn, 29/2. Filling yarn, 18s.
Weight, 1.17 linear yards (0.98 square yard) per pound, finished.
Bleached and napped.



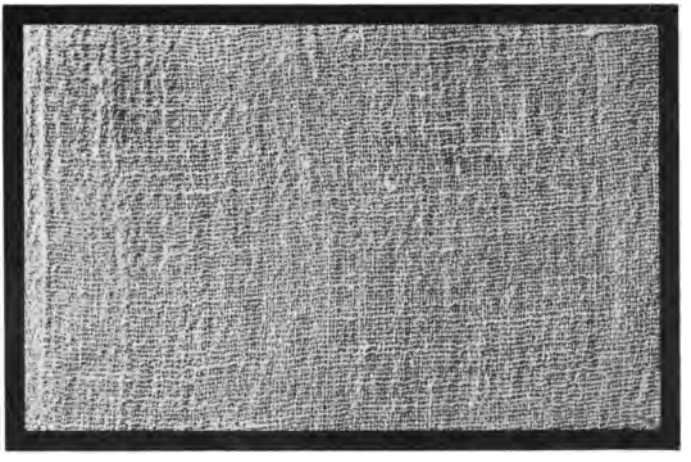
SAMPLE NO. 4.—CRÊPE.

Plain woven. Finished width, 39½ inches.
71 ends and 35 picks per square inch, finished.
Warp yarn, 40s. Filling yarn, hard twisted 13s.
Weight, 3.51 linear yards (3.85 square yards) per pound, finished.
Bleached.



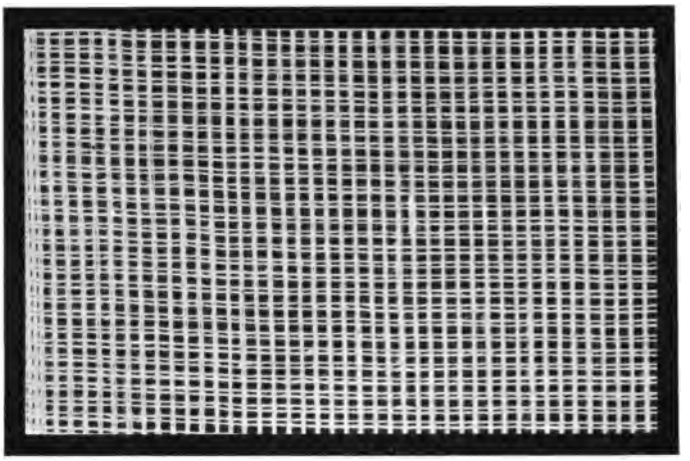
SAMPLE NO. 5.—TENSION REP.

Plain woven with two beams. Finished width, 36 inches.
79 ends and 34 picks per square inch, finished.
Warp yarn, 26s. Filling yarn, 15s.
Weight, 3.94 linear yards (3.94 square yards) per pound, finished.
Bleached and printed.



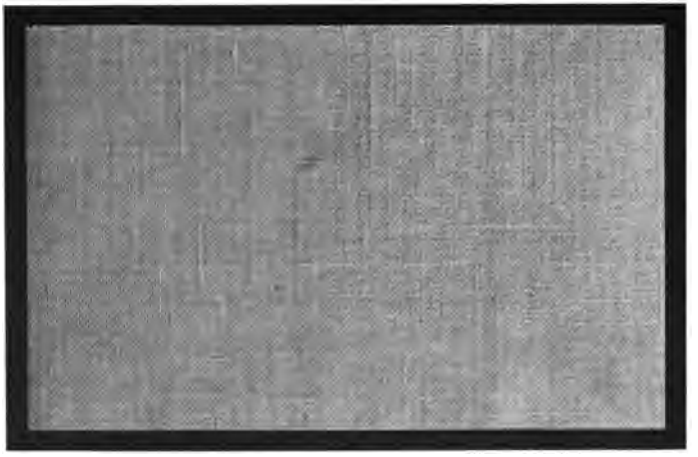
SAMPLE NO. 6.—JAPANESE CRÊPE.

Plain woven. Finished width, 30 inches.
66 warp ends and 43 picks per square inch, finished.
Warp yarn, 32s. Filling yarn, hard twisted 19s.
Weight, 5.32 linear yards (4.43 square yards) per pound, finished.
Piece-dyed orange.



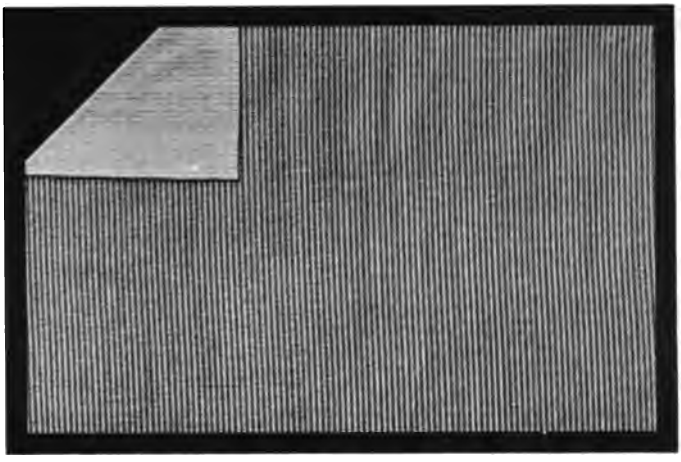
SAMPLE NO. 7.—PENELOPE CANVAS.

Plain woven with square open mesh. Finished width, 22¾ inches.
27 ends and 27 picks per square inch, finished.
Warp yarn, 27/2. Filling yarn, 27/2.
Weight, 7.34 linear yards (4.64 square yards) per pound, finished.
Bleached and stiffened.



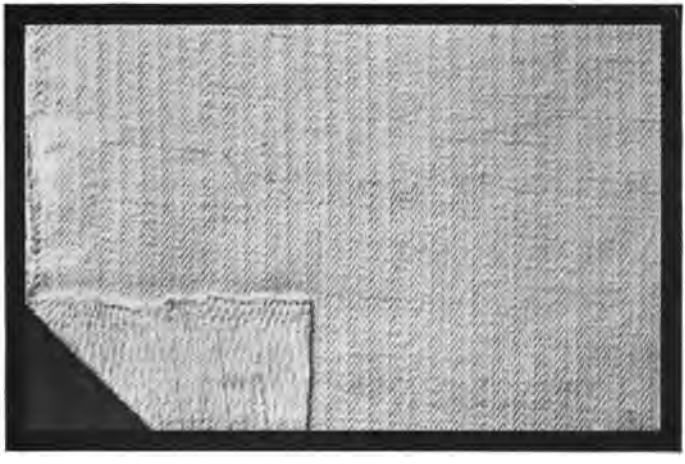
SAMPLE NO. 8.—LONG CLOTH.

Plain woven. Finished width, 36 inches.
65 ends and 61 picks per square inch, finished.
Warp yarn, 35s. Filling yarn, 43s.
Weight, 5.99 linear yards (5.99 square yards) per pound, finished.
Bleached.



SAMPLE NO. 9.—PRINTED SHIRTING.

Plain woven. Finished width, 32 inches.
93 ends and 94 picks per square inch, finished.
Warp yarn, 37s. Filling yarn, 43s.
Weight, 5 linear yards (4.44 square yards) per pound, finished.
Bleached and printed.

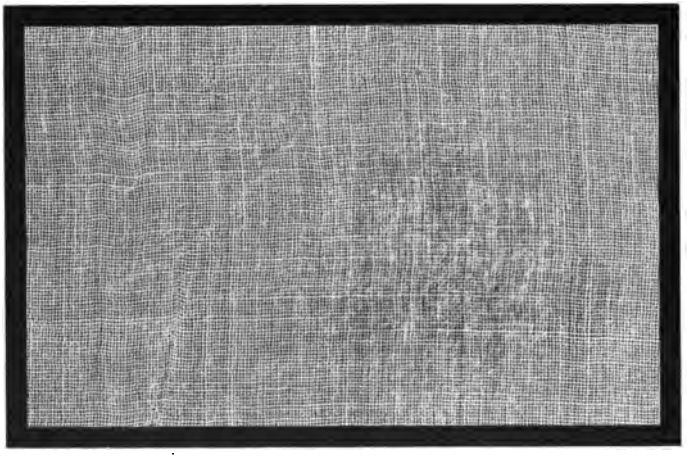


SAMPLE NO. 10.—COUTIL OR CORSET CLOTH.

Herring bone twill. Finished width, 54 inches.
140 ends and 99 picks per square inch, finished.
Warp yarn, 62/2 bleached. Filling yarn, 24s bleached.
Weight, 1.59 linear yards (2.38 square yards) per pound, finished.
Calendered.

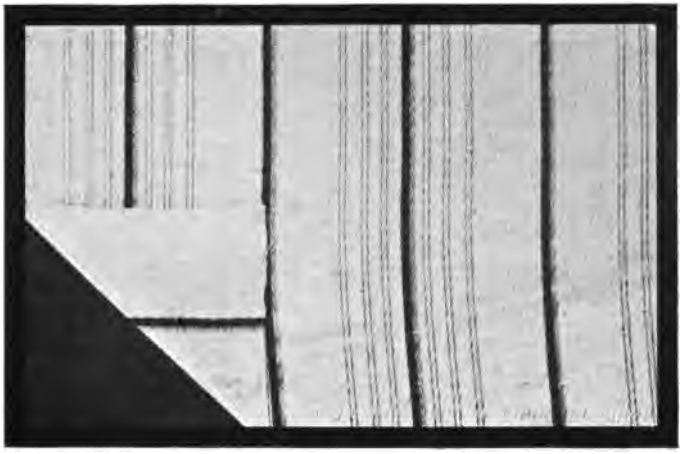
SAMPLE NO. 11.—CORDED SHIRTING.

Plain woven. Finished width, 31 inches.
118 ends and 96 picks per square inch, finished.
Warp yarn, 55s. Warp cord, 22/4. Filling yarn, 64s.
Weight, 5.46 linear yards (4.70 square yards) per pound, finished.
Bleached.



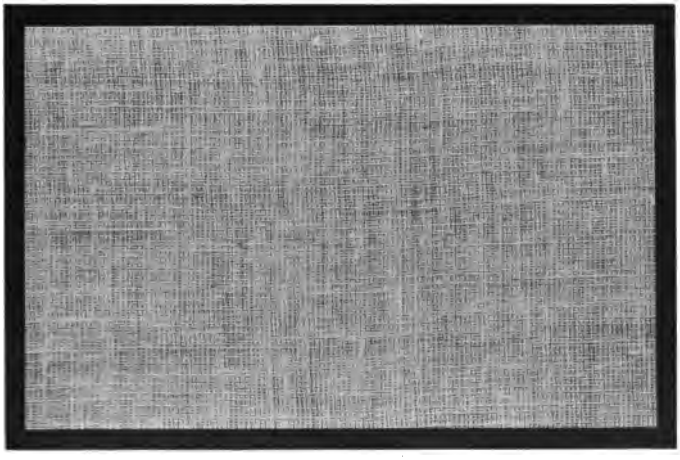
SAMPLE NO. 12.—SINGLE VOILE.

Plain woven. Grey width, 40 inches.
60 ends and 57 picks per square inch, in the grey.
Warp yarn, 53s, hard twisted. Filling yarn, 54s, hard twisted.
Weight, 9 linear yards (10 square yards) per pound, in the grey.
Unbleached.



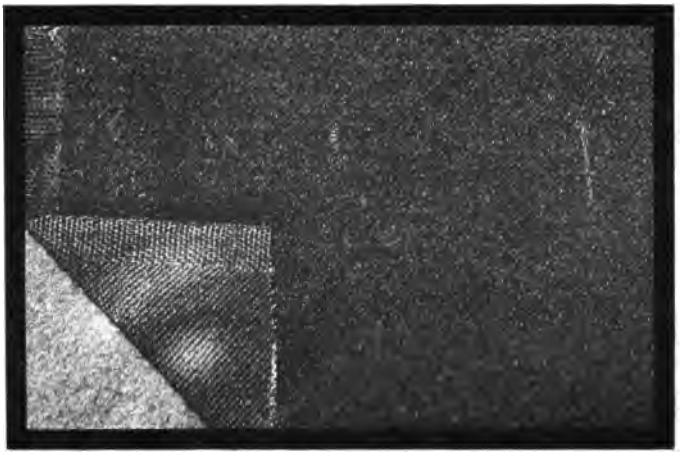
SAMPLE NO. 13.—SLEEVE LINING.

Warp sateen (5-harness). Finished width, 39 inches.
160 ends and 84 picks per square inch, finished.
Warp yarn, 57s. Filling yarn, 47s.
Weight, 4.47 linear yards (4.84 square yards) per pound, finished.
Piece-dyed, mercerized, and printed.



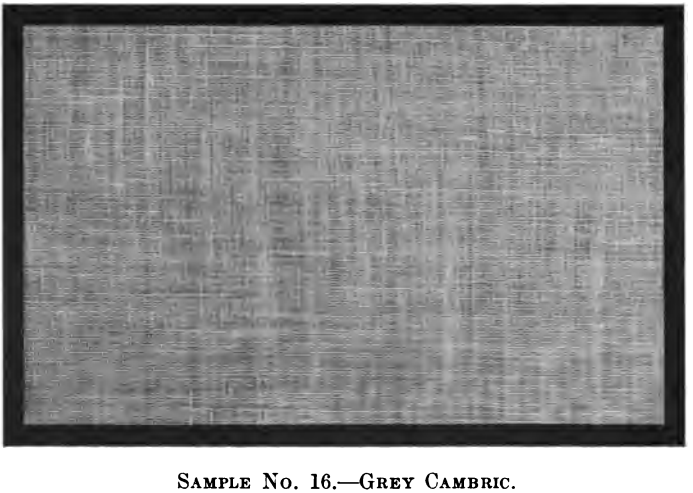
SAMPLE NO. 14.—EMBROIDERY MUSLIN.

Plain woven, with center selvage for splitting. Grey width, 53 inches.
83 ends and 65 picks per square inch, in the grey.
Warp yarn, 54s. Filling yarn, 66s.
Weight, 5.89 linear yards (8.67 square yards) per pound, in grey.
Unbleached.



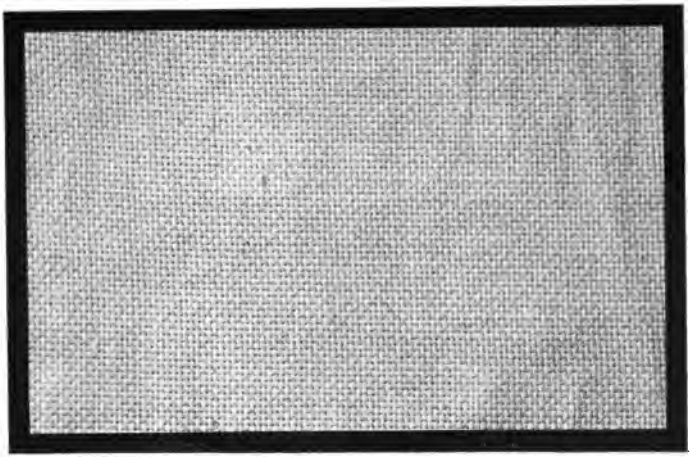
SAMPLE NO. 15.—VENETIAN LINING.

Warp sateen (8-harness). Finished width, 32 inches.
172 ends and 74 picks per square inch, finished.
Warp yarn, 80/2. Filling yarn, 26s.
Weight, 3.42 linear yards (3.04 square yards) per pound, finished.
Piece-dyed, mercerized, and schreinered. Marquis de Luxe finish.



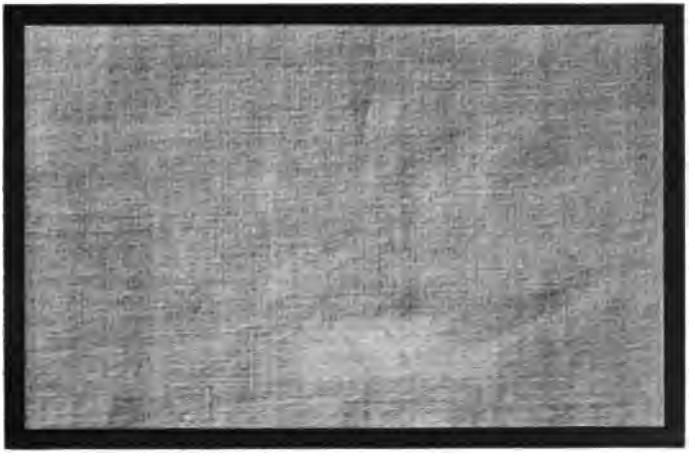
SAMPLE NO. 16.—GREY CAMBRIC.

Plain woven. Grey width, 52½ inches.
93 ends and 83 picks per square inch, in the grey.
Warp yarn, 54s. Filling yarn, 64s.
Weight, 5.22 linear yards (7.61 square yards) per pound, in the grey.
Unbleached.



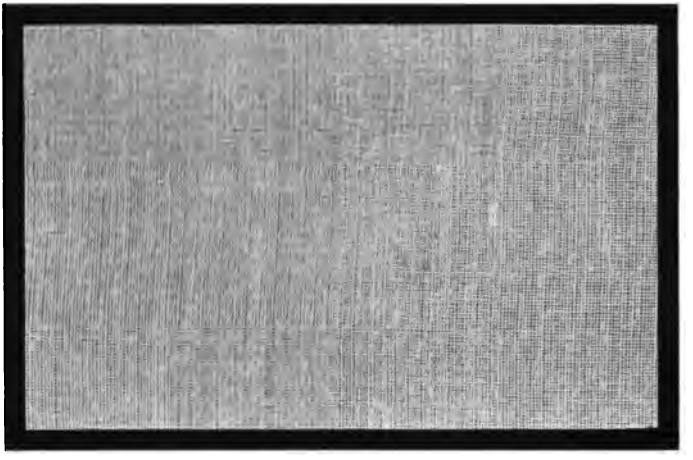
SAMPLE NO. 17.—MATTE SHIRTING.

Plain basket weave. Finished width, 36 inches.
132 ends and 60 picks per square inch, finished.
Warp yarn, 84/2. Filling yarn, 41/2.
Weight, 3.72 linear yards (3.72 square yards) per pound, finished.
Bleached and mercerized.



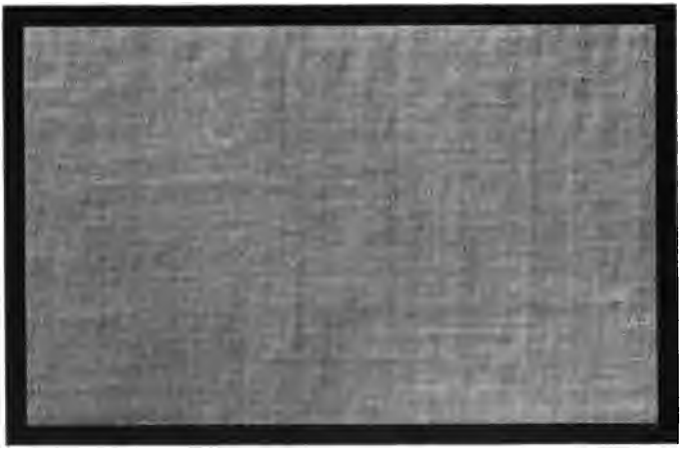
SAMPLE NO. 18.—CAMBRIC.

Plain woven. Finished width, 36 inches.
95 ends and 68 picks per square inch, finished.
Warp yarn, 66s. Filling yarn, 69s.
Weight, 9.14 linear yards (9.14 square yards) per pound, finished.
Bleached.



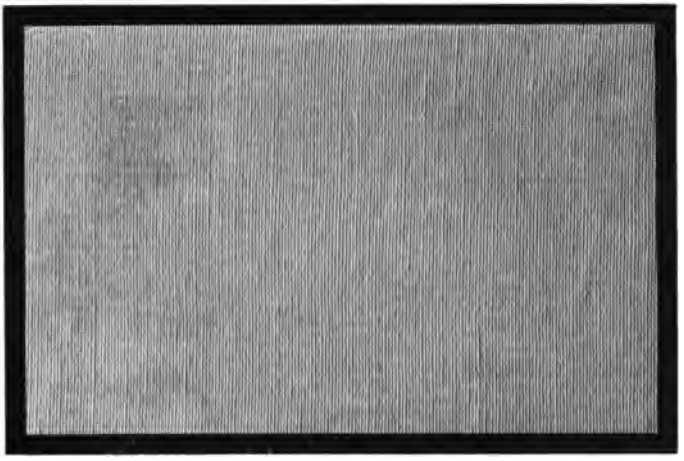
SAMPLE NO. 19.—SEMI-VOILE.

Plain woven. Grey width, 42 inches.
57 ends and 60 picks per square inch, in the grey.
Warp yarn, 47s, hard twisted Filling yarn, 94/2, hard twisted.
Weight, 7.75 linear yards (9.04 square yards) per pound, in the grey.
Unbleached.



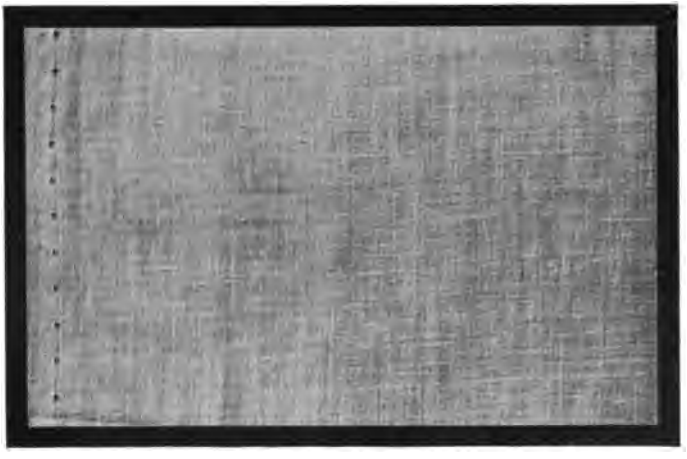
SAMPLE NO. 20.—SATEEN.

Warp sateen (5-harness). Finished width, 39 inches.
172 ends and 90 picks per square inch, finished.
Warp yarn, 77s. Filling yarn, 89s.
Weight, 6.15 linear yards (6.66 square yards) per pound, finished.
Bleached, mercerized, and schreinered.



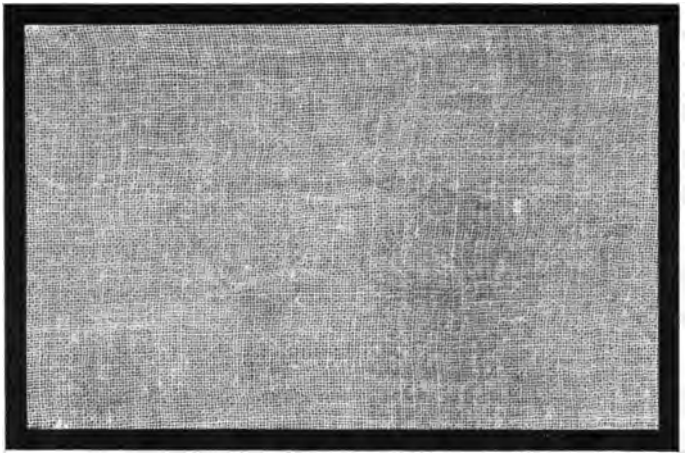
SAMPLE NO. 21.—POPLIN.

Plain woven. Finished width, 54 inches.
183 ends and 58 picks per square inch, finished.
Warp yarn, 87/2. Filling yarn, 67/2.
Weight, 2.48 linear yards (3.72 square yards) per pound, finished.
Bleached, piece-dyed, and mercerized.



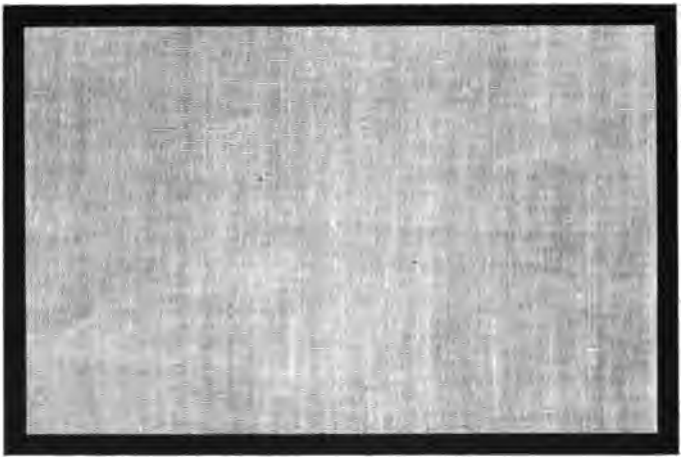
SAMPLE NO. 22.—TYPEWRITER CAMBRIC.

Plain woven. Finished width, 37 inches.
120 ends and 131 picks per square inch, finished.
Warp yarn, 78s. Filling yarn, 103s.
Weight, 7.41 linear yards (7.61 square yards) per pound, finished.
Bleached.



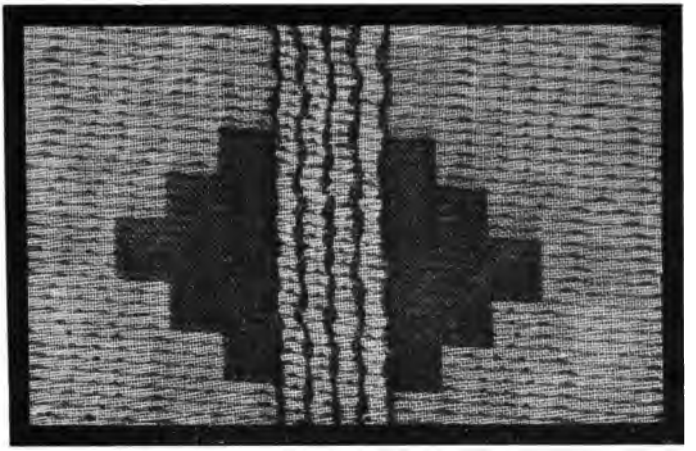
SAMPLE NO. 23.—PLY VOILE.

Plain woven. Grey width, 42½ inches.
59 ends and 57 picks per square inch, in the grey.
Warp yarn, 93/2, hard twisted. Filling yarn, 104/2, hard twisted.
Weight, 7.32 linear yards (8.64 square yards) per pound, in the grey.
Unbleached.



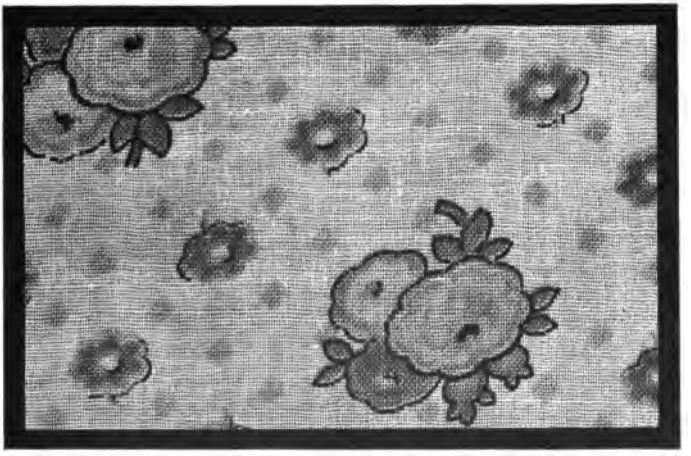
SAMPLE NO. 24.—LAWN.

Plain woven. Finished width, 38 inches.
107 ends and 93 picks per square inch, finished.
Warp yarn, 82s. Filling yarn, 100s.
Weight, 9.76 linear yards (10.30 square yards) per pound, finished.
Piece-dyed pink.



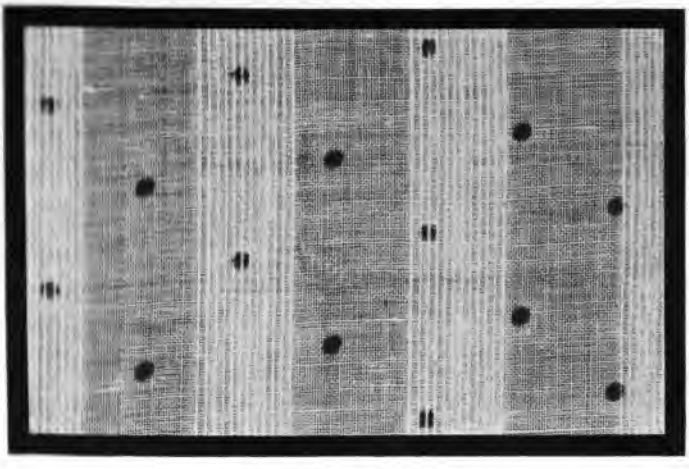
SAMPLE NO. 25.—SEMI-VOILE.

Plain woven. Finished width, 38 inches.
65 ends and 57 picks per square inch, finished.
Warp yarn, 80s, hard twisted. Filling yarn, 106/2, hard twisted.
Weight, 11.22 linear yards (11.84 square yards) per pound, finished.
Bleached, and printed (brown, lavender, and blue).



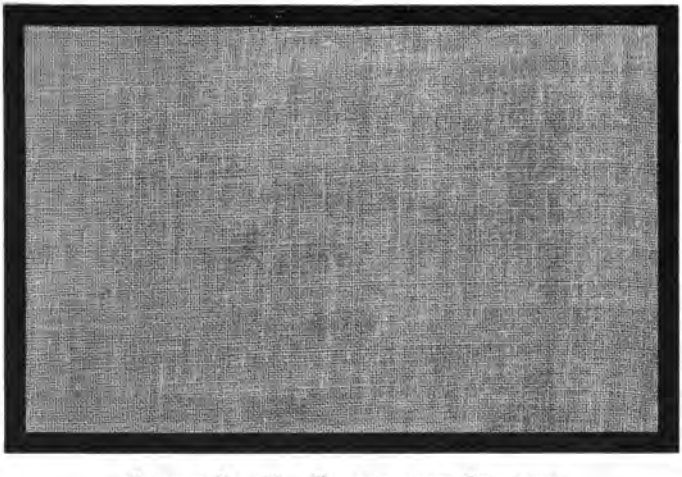
SAMPLE NO. 26.—PLY VOILE.

Plain woven. Finished width, 39 inches.
68 ends and 58 picks per square inch, finished.
Warp yarn, 102/2, hard twisted. Filling yarn, 94/2, hard twisted.
Weight, 7.97 linear yards (8.64 square yards) per pound, finished.
Bleached, and printed (pink, green, light green, yellow, black, and lavender).



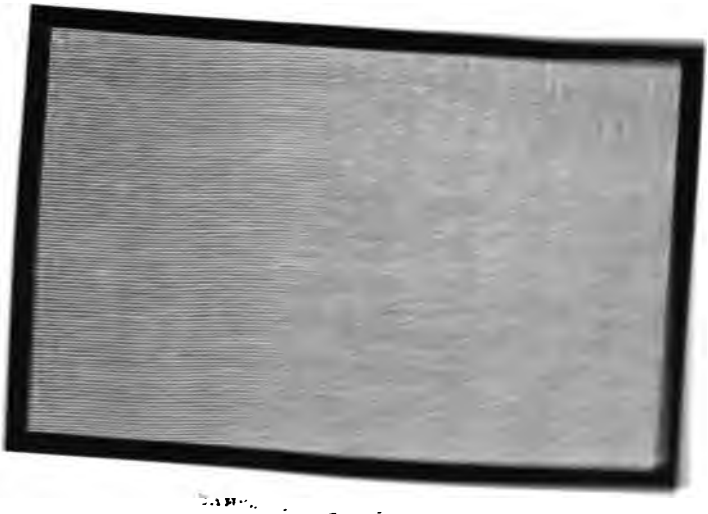
SAMPLE NO. 27.—DIMITY.

Plain woven. Finished width, 28 inches.
91 ends and 75 picks per square inch, finished.
Warp yarn, 85s (warp cords are formed by 3 ends of regular warp). Filling yarn, 132s.
Weight, 17.15 linear yards (13.33 square yards) per pound, finished.
Bleached, and printed with violet dots.



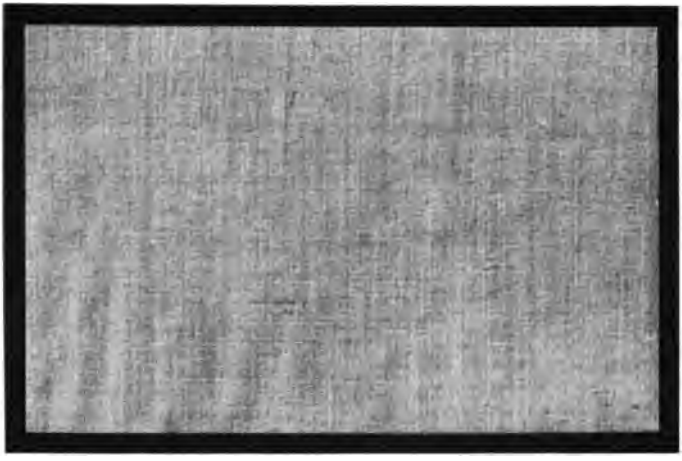
SAMPLE NO. 28.—TRANSPARENT ORGANDY.

Plain woven. Finished width, 44½ inches.
87 ends and 73 picks per square inch, finished.
Warp yarn, 86s. Filling yarn, 125s.
Weight, 11.24 linear yards (13.91 square yards) per pound, finished.
Piece-dyed pink. Permanent organdy finish.



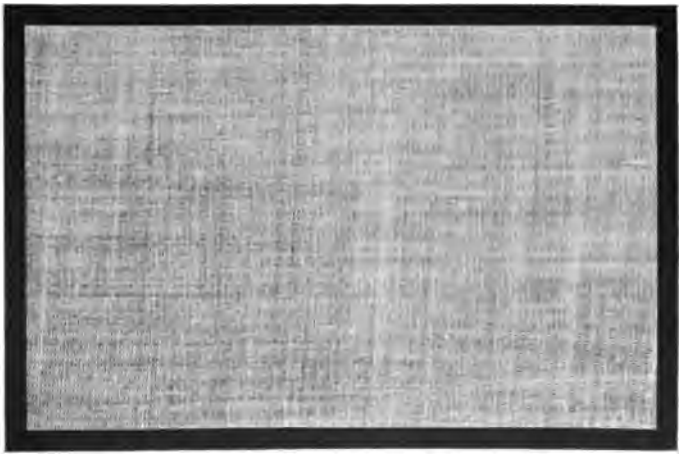
Plain woven.
60 ends and
Warp yarn
Weight
Bleached.

Plain woven.
110 ends and
Warp yarn.
Weight, 10.6
Bleached.



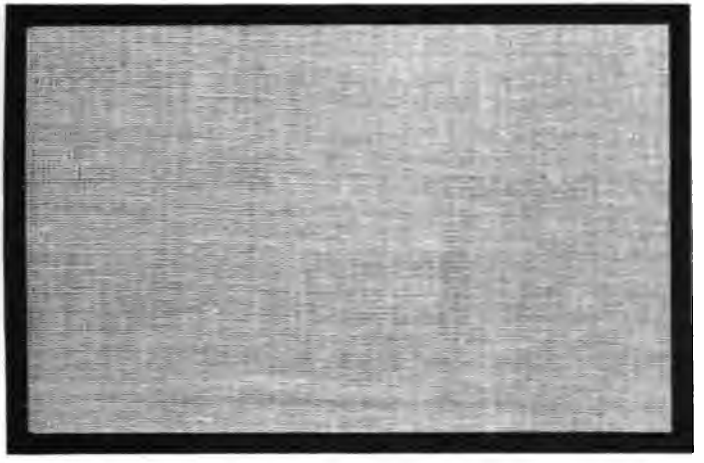
SAMPLE NO. 31.—TYPEWRITER CAMBRIC.

Plain woven. Grey width, 39 inches.
142 ends and 156 picks per square inch, in the grey.
Warp yarn, 90s. Filling yarn, 140s.
Weight, 7.03 linear yards (7.61 square yards) per pound, in the grey.
Unbleached.



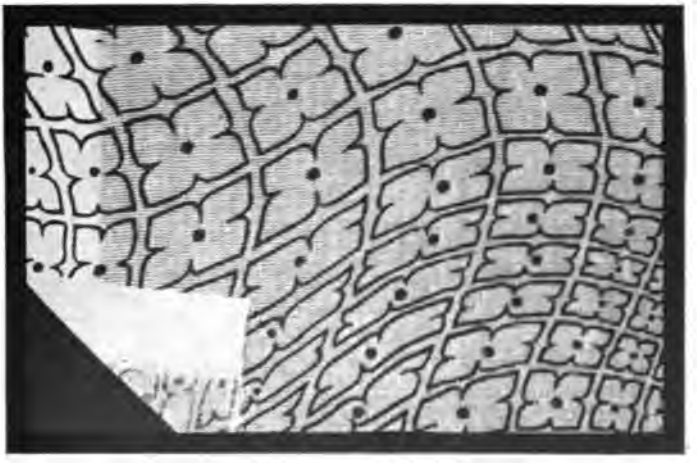
SAMPLE NO. 32.—COTTON MULL.

Plain woven. Finished width, 44 inches.
94 ends and 92 picks per square inch, finished.
Warp yarn, 87s. Filling yarn, 117s.
Weight, 10.07 linear yards (12.31 square yards) per pound, finished.
Bleached and mercerized.



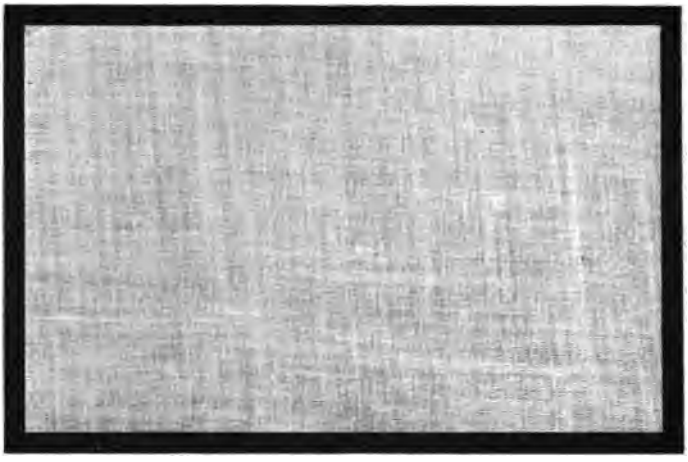
SAMPLE No. 33.—FRENCH LAWN.

Plain woven. Finished width, 47 inches.
78 ends and 76 picks per square inch, finished.
Warp yarn, 99s. Filling yarn, 107s.
Weight, 11.67 linear yards (15.24 square yards) per pound, finished.
Bleached.



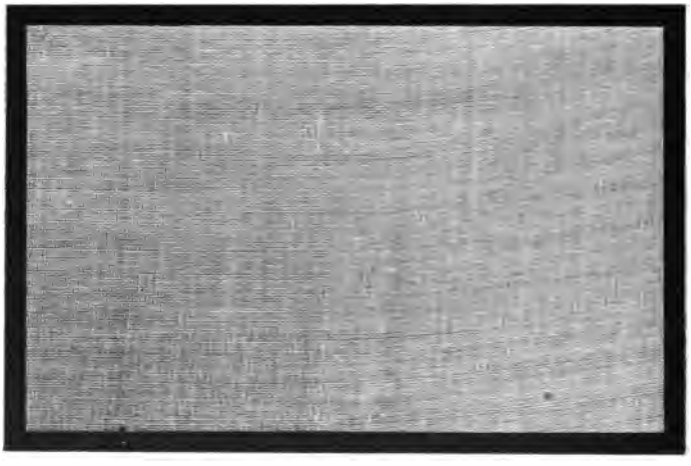
SAMPLE No. 34. PLY VOILE.

Plain woven. Finished width, 38 inches.
69 ends and 56 picks per square inch, finished.
Warp yarn, 110/2, hard twisted. Filling yarn, 110/2, hard twisted.
Weight, 8.81 linear yards (9.30 square yards) per pound, finished.
Bleached, and printed with a wavy blue design.



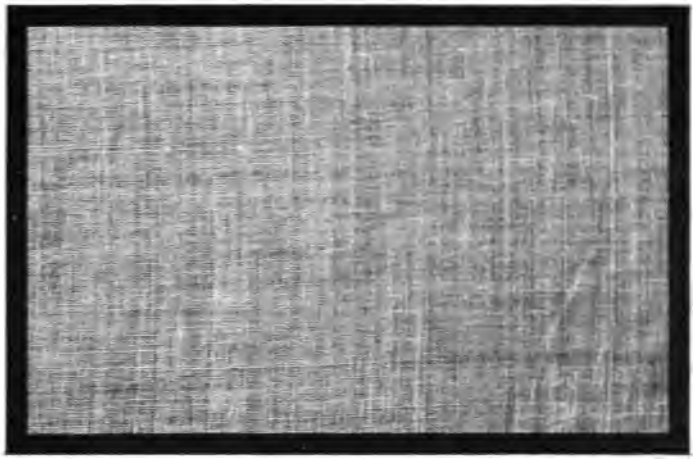
SAMPLE NO. 35.—BATISTE.

Plain woven. Finished width, 46 inches.
97 ends and 94 picks per square inch, finished.
Warp yarn, 88s. Filling yarn, 124s.
Weight, 9.64 linear yards (12.32 square yards) per pound, finished.
Bleached and mercerized.



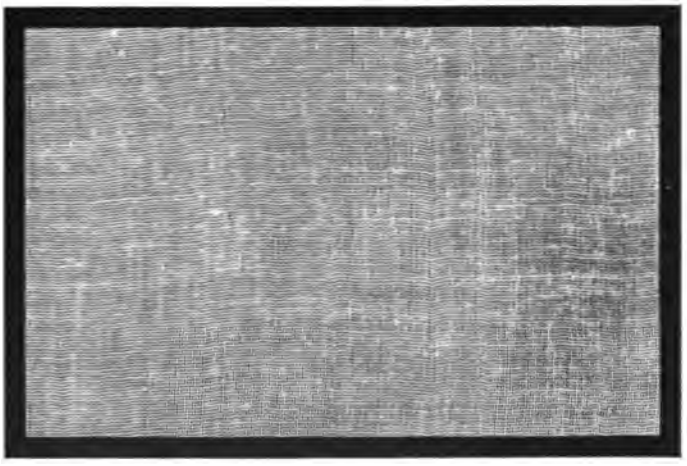
SAMPLE NO. 36.—TRANSPARENT ORGANDY.

Plain woven. Finished width, 52 inches.
91 ends and 85 picks per square inch, finished.
Warp yarn, 88s. Filling yarn, 128s.
Weight, 9.23 linear yards (13.33 square yards) per pound, finished.
Bleached. Permanent organdy finish.



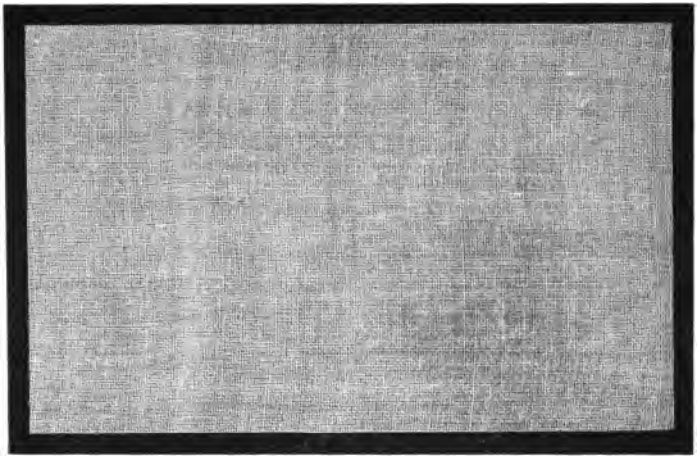
SAMPLE NO. 37.—MUSLIN.

Plain woven. Grey width, 40 inches.
100 ends and 85 picks per square inch, in the grey.
Warp yarn, 98s. Filling yarn, 132s.
Weight, 12 linear yards (13.33 square yards) per pound, in the grey.
Unbleached.



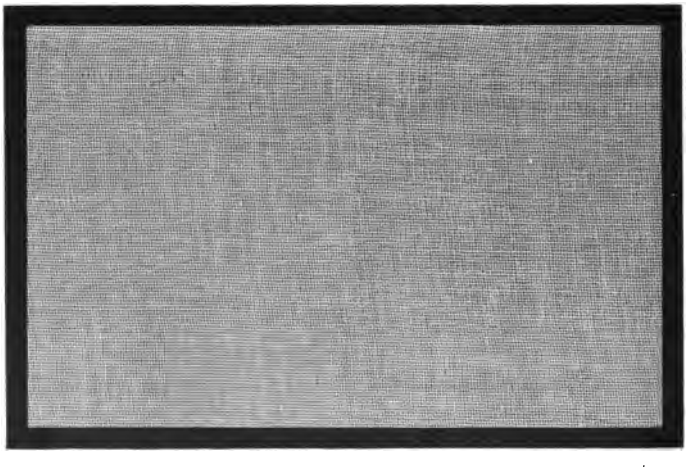
SAMPLE NO. 38.—PLY VOILE.

Plain woven. Finished width, 43 inches.
65 ends and 60 picks per square inch, finished.
Warp yarn, 138/2, hard twisted. Filling yarn, 114/2, hard twisted.
Weight, 9.24 linear yards (11.04 square yards) per pound, finished.
Bleached.



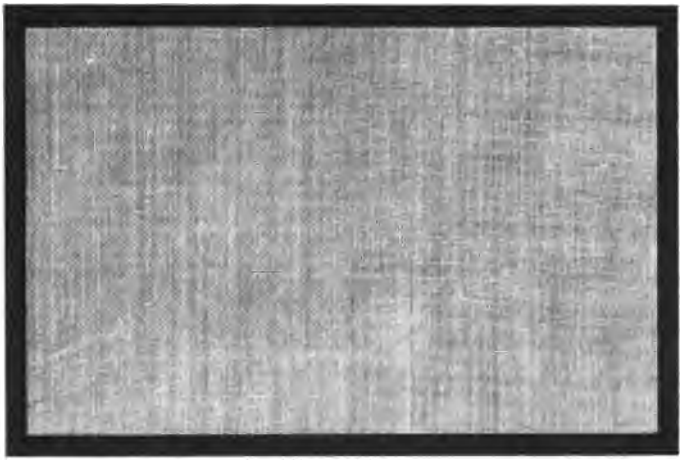
SAMPLE NO. 39.—TRANSPARENT ORGANDY.

Plain woven. Finished width, 45 inches.
90 ends and 87 picks per square inch, finished.
Warp yarn, 108s. Filling yarn, 146s.
Weight, 12.80 linear yards (16 square yards) per pound, finished.
Bleached. Permanent organdy finish.



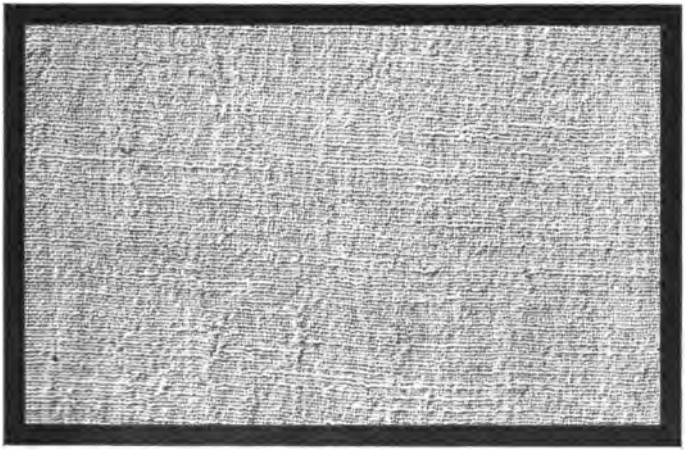
SAMPLE NO. 40.—PLY VOILE.

Plain woven. Finished width, 54½ inches.
68 ends and 61 picks per square inch, finished.
Warp yarn, 158/2, hard twisted. Filling yarn, 143/2, hard twisted.
Weight, 8.81 linear yards (13.33 square yards) per pound, finished.
Bleached.



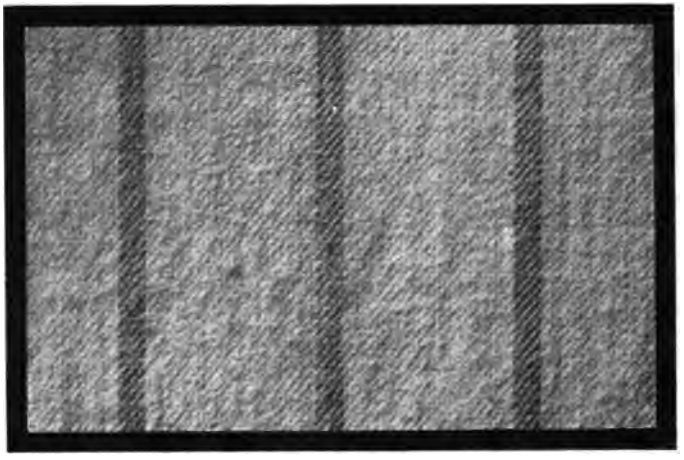
SAMPLE NO. 41.—CHIFFON MULL.

Plain woven. Finished width, 45 inches.
96 ends and 96 picks per square inch, finished.
Warp yarn, 230s. Filling yarn, 230s.
Weight, 21.34 linear yards (26.67 square yards) per pound, finished.
Piece-dyed ecru. Mercerized.



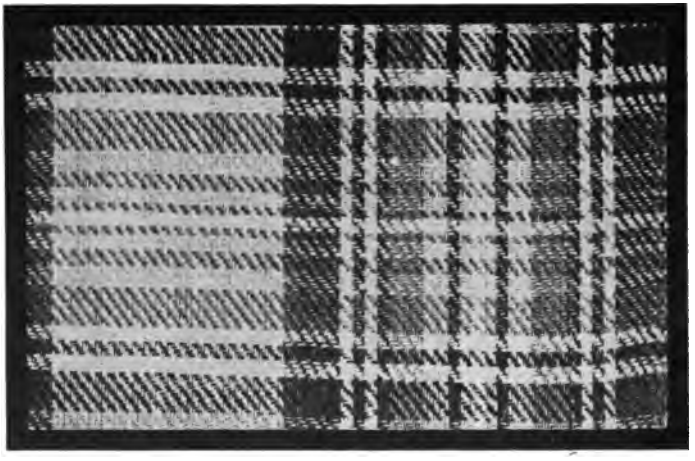
SAMPLE NO. 42.—JAPANESE CRÊPE.

Plain woven. Finished width, 30 inches.
76 ends and 52 picks per square inch, finished.
Warp yarn, 30s, dyed. Filling yarn, 18s, hard twisted, bleached.
Weight, 4.21 linear yards (3.52 square yards) per pound, finished.
Lavender warp and white filling.



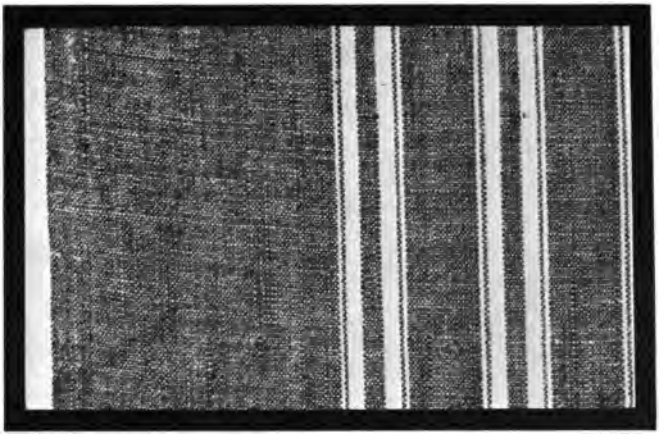
SAMPLE NO. 43.—STRIPED FLANNELET.

Twill woven (4-harness). Finished width, 31 inches.
84 ends and 70 picks per square inch, finished.
Warp yarn, 18s, dyed. Filling yarn, 28s, soft twisted, bleached.
Weight, 3.44 linear yards (2.96 square yards) per pound, finished.
Light blue warp with lavender stripes and white filling. Napped on both sides.



SAMPLE NO. 44.—TARTAN PLAID.

Twill woven (4-harness) on box loom. Finished width, 36 inches.
65 ends and 51 picks per square inch, finished.
Warp yarn, 21s, dyed, 21s, bleached. Filling yarn, 26s, dyed, 26s, bleached.
Weight, 4.21 linear yards (4.21 square yards) per pound, finished.
Green, yellow, black, white, and red warp; lavender, yellow, black, white, green, and red filling.

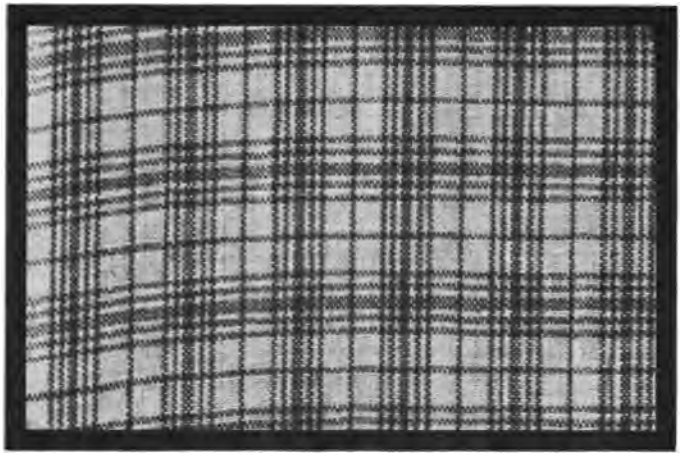


SAMPLE NO. 45.—STRIPED TICKING.

Plain woven. Finished width, 32 inches.
97 ends and 70 picks per square inch, finished.
Warp yarn, 24s, vat dyed, 24s bleached. Filling yarn, 33s, bleached.
Weight, 3.71 linear yards (3.30 square yards) per pound, finished.
Blue and white warp; white filling.

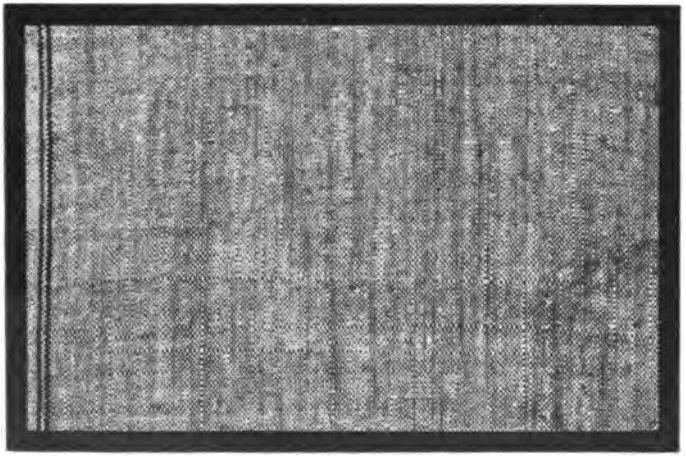
SAMPLE NO. 46.—TARTAN PLAID.

Twill woven (4-harness) on box loom. Finished width, 36 inches.
56 ends and 62 picks per square inch, finished.
Warp yarn, 32s, dyed. Filling yarn, 26s, dyed.
Weight, 5.33 linear yards (5.33 square yards) per pound, finished.
Red, black, blue, and green in both warp and filling.



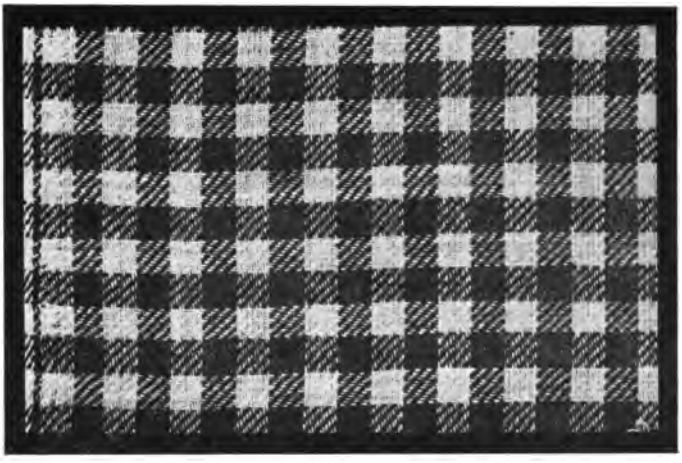
SAMPLE NO. 47.—GINGHAM CHECK.

Plain woven on box loom. Finished width, 31 inches.
72 ends and 61 picks per square inch, finished.
Warp yarn, 28s, dyed, 28s, bleached. Filling yarn, 34s, dyed, 34s, bleached.
Weight, 5.71 linear yards (4.92 square yards) per pound, finished.
Black and white in both warp and filling.



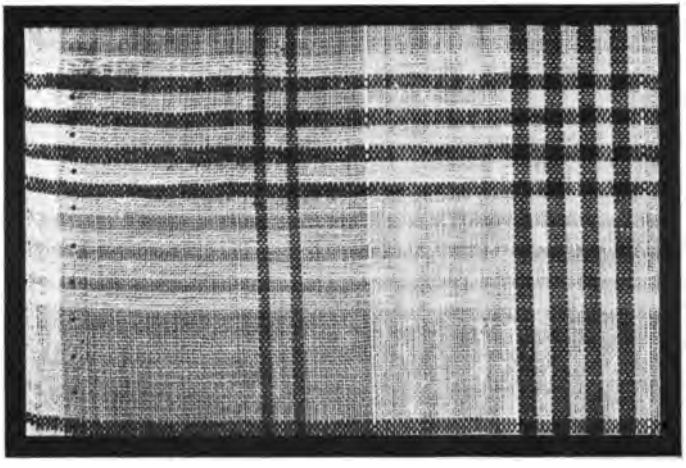
SAMPLE NO. 48.—NANKIN TICKING.

Plain woven. Finished width, 35¼ inches.
85 ends and 76 picks per square inch, finished.
Warp yarn, 28s, bleached. Filling yarn, 35s, dyed.
Weight, 4.13 linear yards (4.04 square yards) per pound, finished.
White warp and red filling.



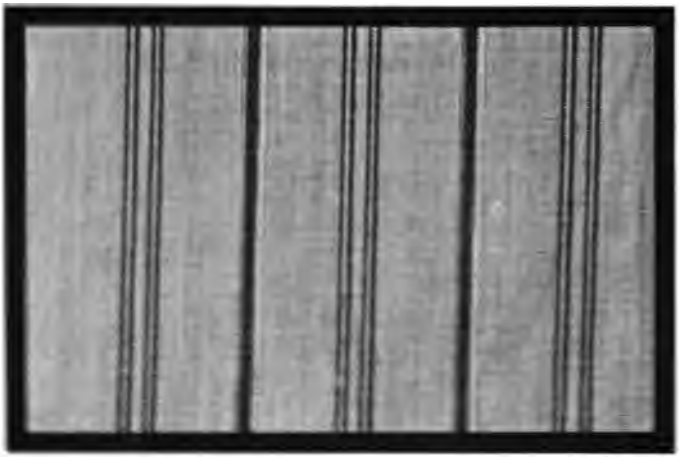
SAMPLE NO. 49.—SHEPHERD CHECK.

Twill woven (4-harness) on box loom. Finished width, 31 inches.
70 ends and 67 picks per square inch, finished.
Warp yarn, 29s, dyed, 29s, bleached. Filling yarn, 33s, dyed, 33s, bleached.
Weight, 5.81 linear yards (5 square yards) per pound, finished.
Black and white in both warp and filling.



SAMPLE NO. 50.—PLAID GINGHAM.

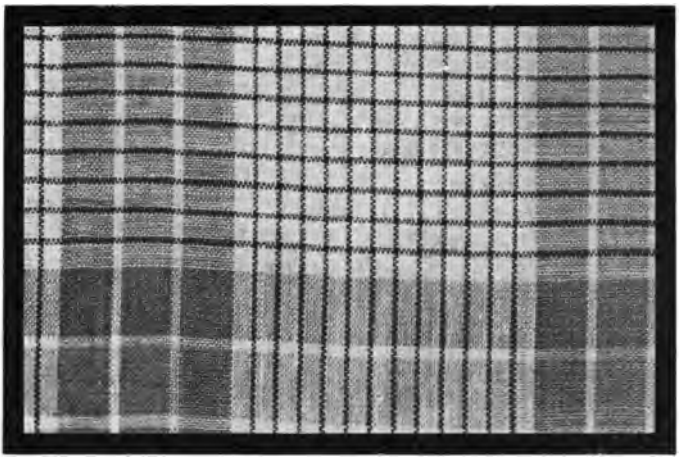
Plain woven on box loom. Finished width, 31½ inches.
68 ends and 57 picks per square inch, finished.
Warp yarn, 31s, dyed, 31s, bleached. Filling yarn, 41s, dyed, 41s, bleached.
Weight, 6.90 linear yards (6.04 square yards) per pound, finished.
White, black, blue, and brown in both warp and filling.



Sample No. 5. [illegible]

Plain weave. [illegible]
Warp and filling yarn, all bleached. Filling yarn, all bleached.
Right and wrong sides alike.

[illegible]



SAMPLE NO. 53.—GINGHAM CHECK.

Plain woven on box loom. Finished width, 32 inches.

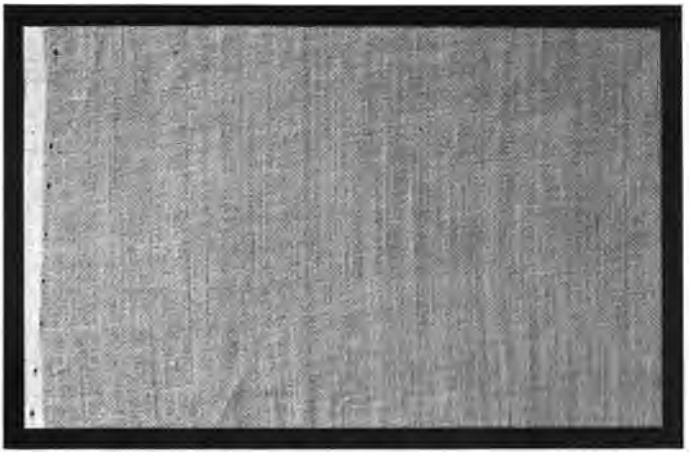
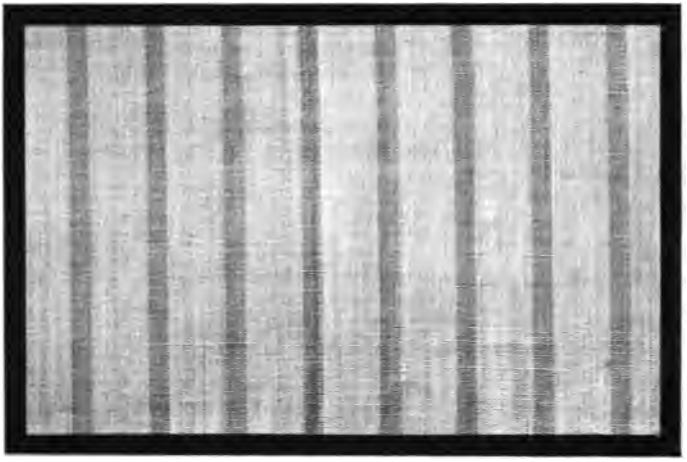
Warp yarn, 39s, dyed, 39s, bleached. Filling yarn, 43s, dyed, 43s, bleached.
Weight, 6.92 linear yards (6.15 square yards) per pound, finished.
Brown, white, green, and black in both warp and filling.



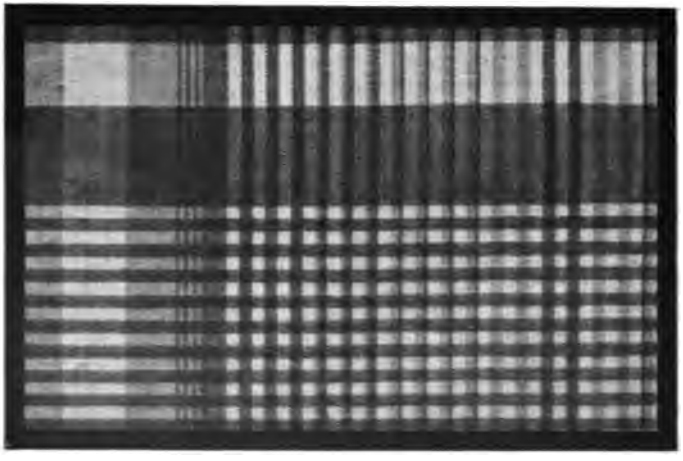
SAMPLE NO. 54.—SOLID-COLOR GINGHAM.

Plain woven. Finished width, 28 inches.
87 ends and 70 picks per square inch, finished.
Warp yarn, 37s, vat dyed. Filling yarn, 55s, vat dyed.
Weight, 7.91 linear yards (6.15 square yards) per pound, finished.
Light blue in both warp and filling. White warp selvage.



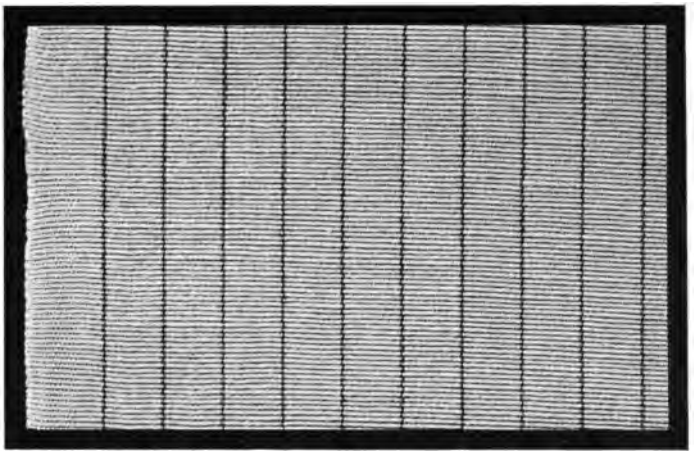
SAMPLE NO. 55.—STRIPED SHIRTING.

Plain woven. Finished width, 32 inches.
92 ends and 86 picks per square inch, finished.
Warp yarn, 43s, dyed, 43s, bleached. Filling yarn, 58s, bleached.
Weight, 6.78 linear yards (6.03 square yards) per pound, finished.
White and blue warp; white filling.



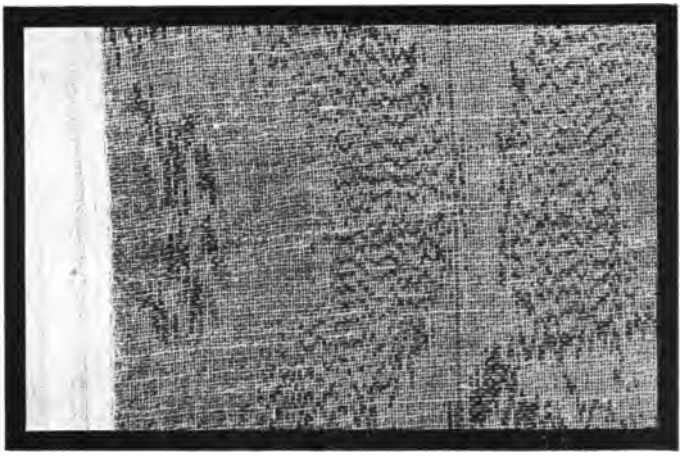
SAMPLE NO. 56.—FINE PLAID GINGHAM.

Plain woven on box loom. Finished width, 32 inches.
94 ends and 92 picks per square inch, finished.
Warp yarn, 43s, dyed, 43s, bleached. Filling yarn, 58s, dyed, 58s, bleached.
Weight, 6.42 linear yards 5.71 square yards per pound, finished.
Blue, white, black, and yellow in both warp and filling.



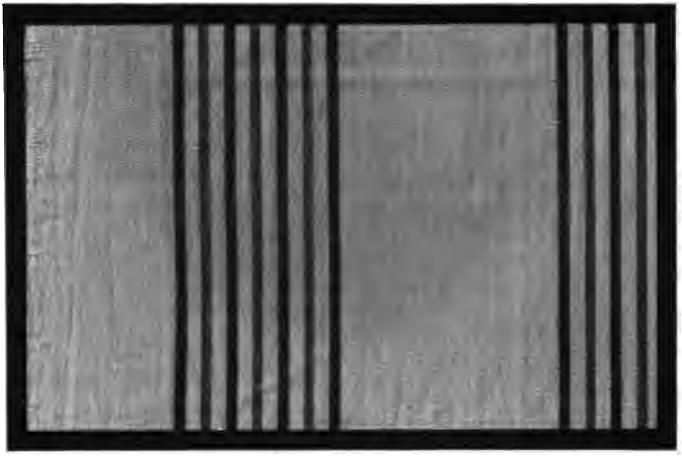
SAMPLE NO. 57.—STRIPED POPLIN.

Plain woven. Finished width, 54 inches.
168 ends and 38 picks per square inch, finished.
Warp yarn, 90/2, dyed. Filling yarn, 33/3, dyed.
Weight, 2.05 linear yards (3.07 square yards) per pound, finished.
Tan warp with blue stripes; tan filling. Mercerized.



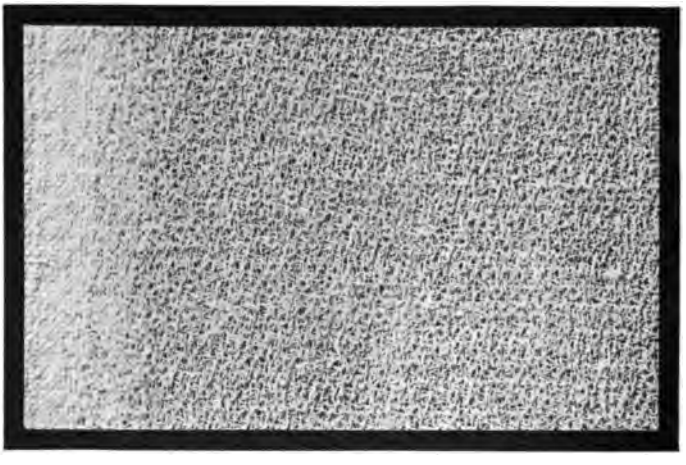
SAMPLE NO. 58.—WARP-PRINTED CRÊPE VOILE.

Plain woven. Finished width, 36 inches.
61 ends and 55 picks per square inch, finished.
Warp yarn, 107/2, hard twisted, printed. Filling yarn, hard twisted, 86/2, dyed.
Weight, 8.89 linear yards (8.89 square yards) per pound, finished.
Bleached warp printed in red, green, blue, brown, yellow, and black; blue filling.



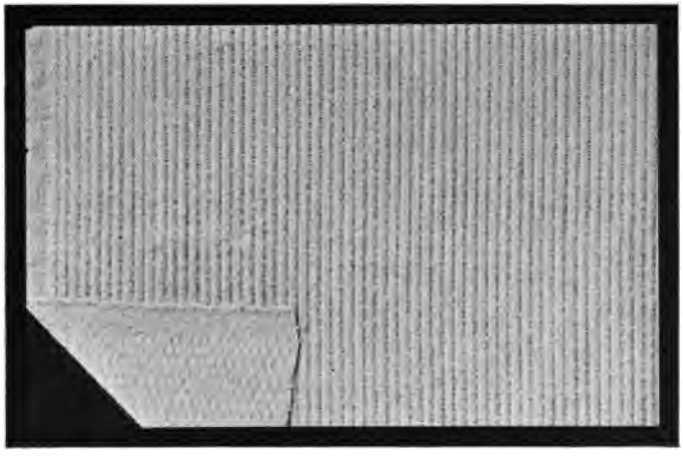
SAMPLE NO. 59.—FINE SHIRTING POPLIN, STRIPED.

Plain woven. Finished width, 31 inches.
147 ends and 76 picks per square inch, finished.
Warp yarn, 105/2, dyed, 105/2, bleached. Filling yarn, 109/2, bleached.
Weight, 5.86 linear yards (5.05 square yards) per pound, finished.
Black, grey, and white warp; white filling. Mercerized.



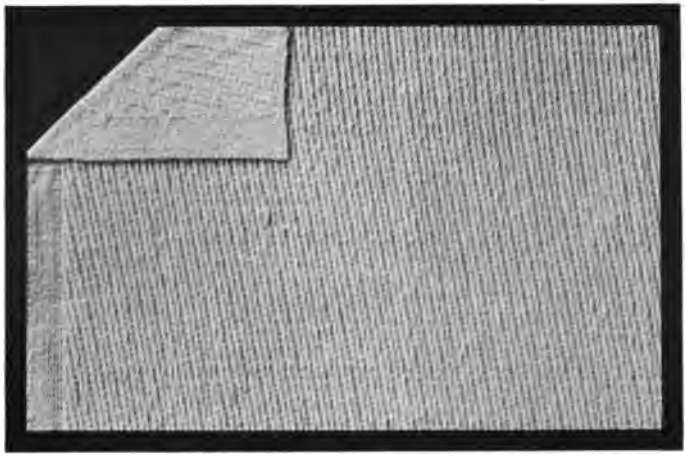
SAMPLE NO. 60.—CRÊPE.

Dobby woven (12-harness) on box loom. Finished width, 38½ inches.
57 ends and 47 picks per square inch, finished.
Warp yarn, 22s, hard twisted. Filling yarn, 21s, hard twisted.
Weight, 3.44 linear yards (3.68 square yards) per pound, finished.
Bleached.



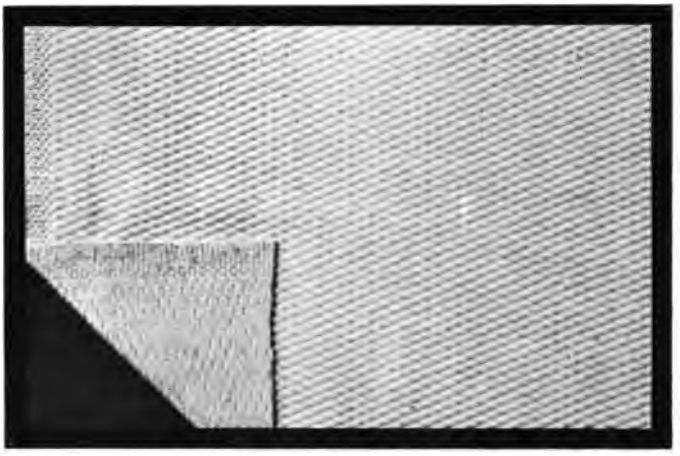
SAMPLE NO. 61.—BEDFORD CORD.

Dobby woven (12-harness). Grey width, 37½ inches.
103 ends and 80 picks per square inch, in the grey.
Warp yarn, 27s. Filling yarn, 38s.
Weight, 3.41 linear yards (3.55 square yards) per pound, in the grey.
Unbleached.



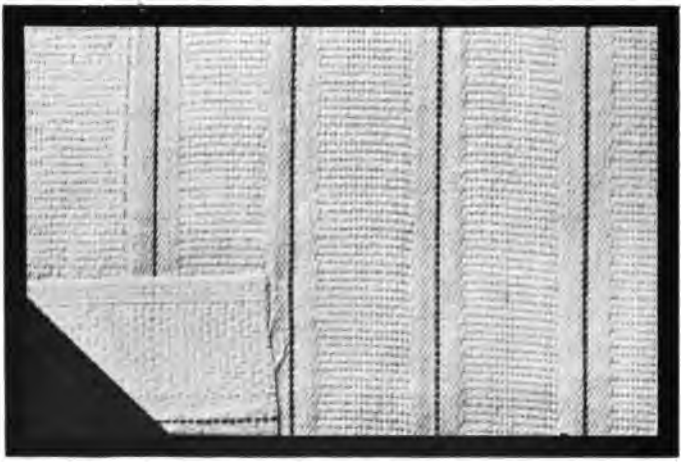
SAMPLE NO. 62.—STEEP TWILL.

Dobby woven (11-harness). Finished width, 39 inches.
148 ends and 64 picks per square inch, finished.
Warp yarn, 33s. Filling yarn, 31s.
Weight, 3.01 linear yards (3.26 square yards) per pound, finished.
Bleached.



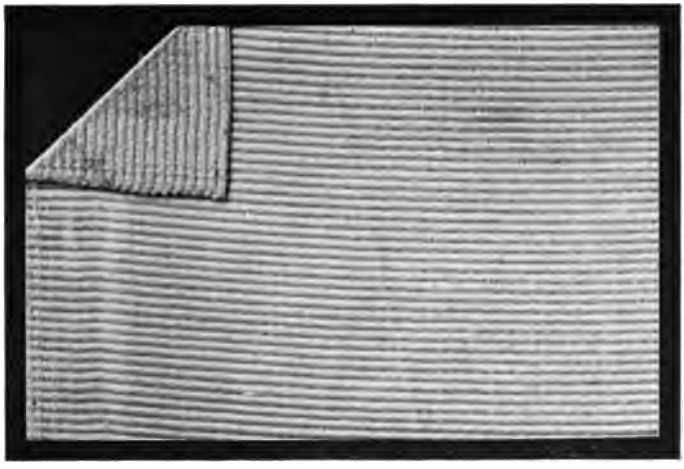
SAMPLE NO. 63.—FANCY PIQUÉ.

Dobby woven on box loom. Finished width, 28 inches.
155 ends and 223 picks per square inch, finished.
Warp yarn, 77s face, 82/2 back. Filling yarn, 90s face, 11s back.
Weight, 2.24 linear yards (1.74 square yards) per pound, finished.
Bleached.



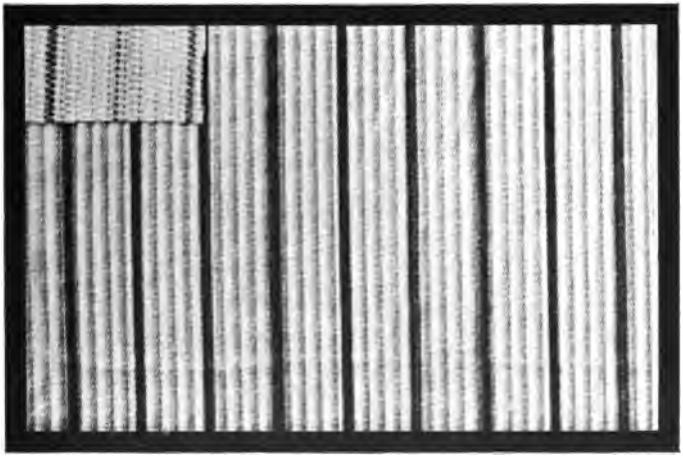
SAMPLE NO. 64.—FANCY OXFORD SHIRTING.

Dobby woven (6-harness). Finished width, 32 inches.
144 ends and 90 picks per square inch, finished.
Warp yarn, 41s, bleached, 80/2, dyed. Filling yarn, 41s, bleached.
Weight, 4.5 linear yards (4 square yards) per pound, finished.
White warp, with turkey red pin stripes; white filling.



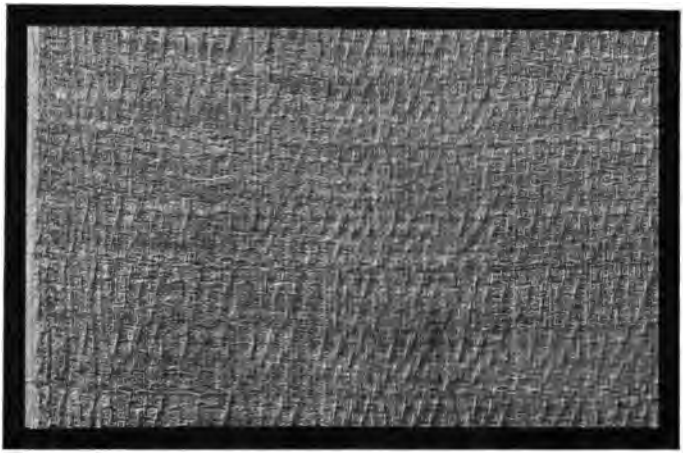
SAMPLE NO. 65.—PIQUÉ VESTING.

Dobby woven on box loom. Finished width, 28 inches.
135 ends and 230 picks per square inch, finished.
Warp yarn, 67s face, 68/2 back. Filling yarn, 78s face, 17s back.
Weight, 2.87 linear yards (2.23 square yards) per pound finished.
Bleached.



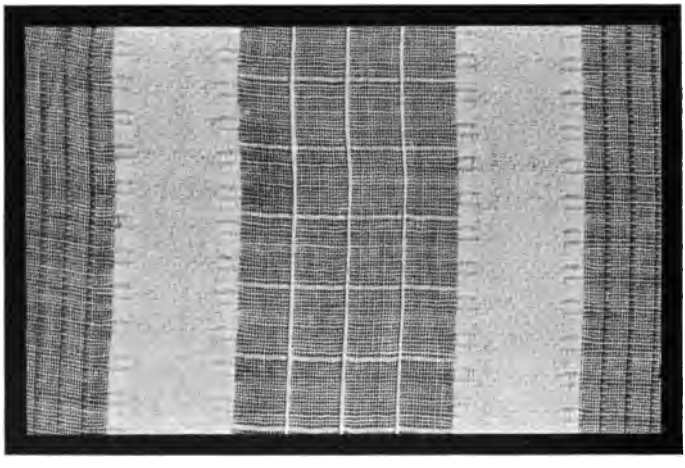
SAMPLE NO. 66.—BEDFORD CORD.

Dobby woven (8-harness). Finished width, 44 inches.
144 ends and 104 picks per square inch, finished.
Warp yarn, 57s; warp stuffing, 45/2. Filling yarn, 43s.
Weight, 3.27 linear yards (4 square yards) per pound, finished.
Bleached, with brown printed stripes.



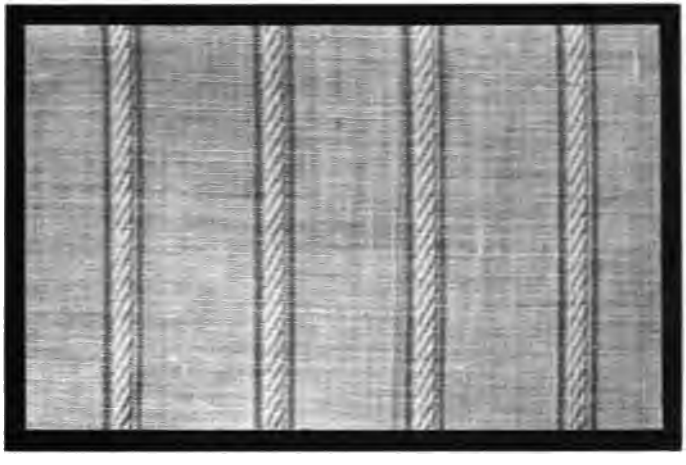
SAMPLE NO. 67.—COLORED JACQUARD SHIRTING.

Jacquard woven. Finished width, 32 inches.
90 ends and 75 picks per square inch, finished.
Warp yarn, 44s, vat dyed. Filling yarn, 55s, bleached.
Weight, 7.5 linear yards (6.67 square yards) per pound, finished.
Lavender warp and white filling.



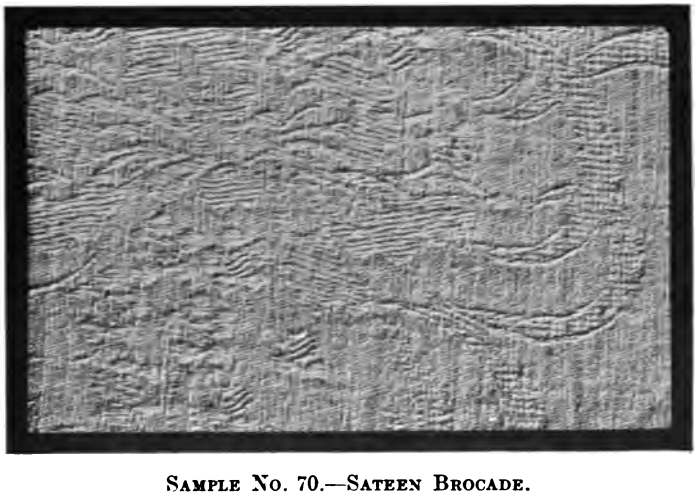
SAMPLE NO. 68.—FANCY STRIPED VOILE.

Dobby woven (14-harness). Finished width, 39 inches.
80 ends and 56 picks per square inch, finished.
Warp yarn, 102/2 bleached; 40/2 and 29/4 bleached and mercerized; 55/2 dyed.
Filling yarn, 54s bleached.
Weight, 5.51 linear yards (5.97 square yards) per pound, finished.
White warp with lavender stripes and mercerized white stripes; white filling.



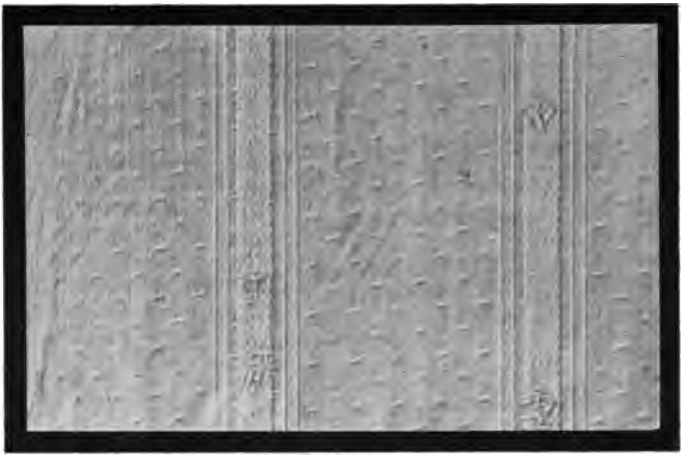
SAMPLE NO. 69.—DOBBY SHIRTING STRIPES.

Dobby woven (10-harness). Finished width, 32 inches.
103 ends and 88 picks per square inch, finished.
Warp yarn, 62s, bleached; 86/2, dyed; 72/2, bleached, mercerized. Filling yarn, 56s bleached.
Weight, 6.84 linear yards (6.08 square yards) per pound, finished.
Lavender, white, and white mercerized warp; white filling.



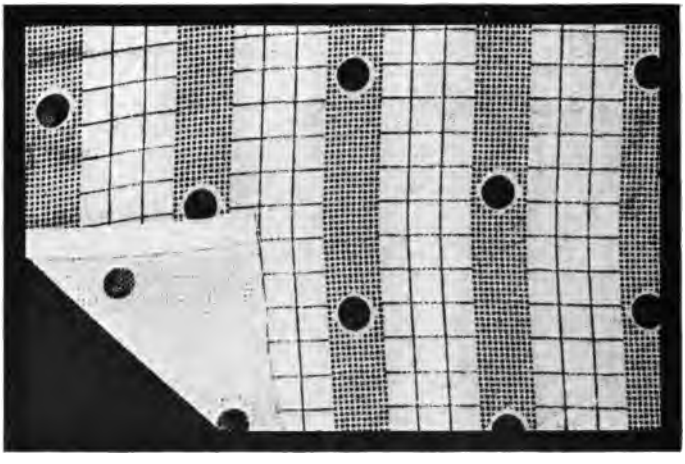
SAMPLE NO. 70.—SATEEN BROCADE.

Jacquard woven. Grey width, 39 inches.
87 ends and 140 picks per square inch, in the grey.
Warp yarn, 54s. Filling yarn, 68s.
Weight, 5.46 linear yards (5.92 square yards) per pound, in the grey.
Unbleached.



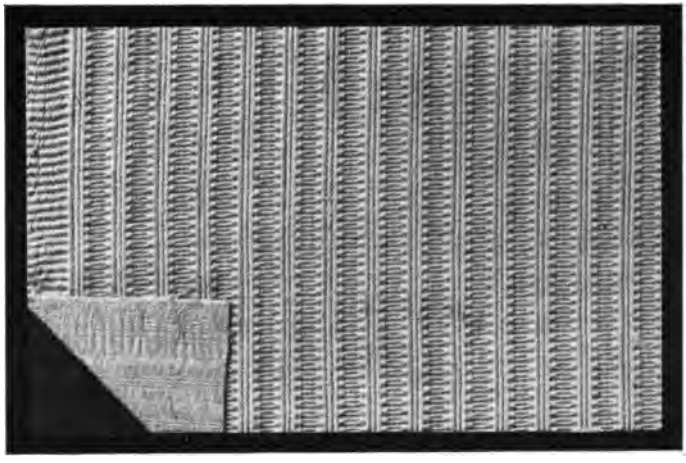
SAMPLE NO. 71.—JACQUARD SHIRTING.

Jacquard woven. Finished width, 32 inches.
124 ends and 118 picks per square inch, finished.
Warp yarn, 63s, with 55/2 in warp cords. Filling yarn, 66s.
Weight, 6.21 linear yards (5.52 square yards) per pound, finished.
Bleached and mercerized.



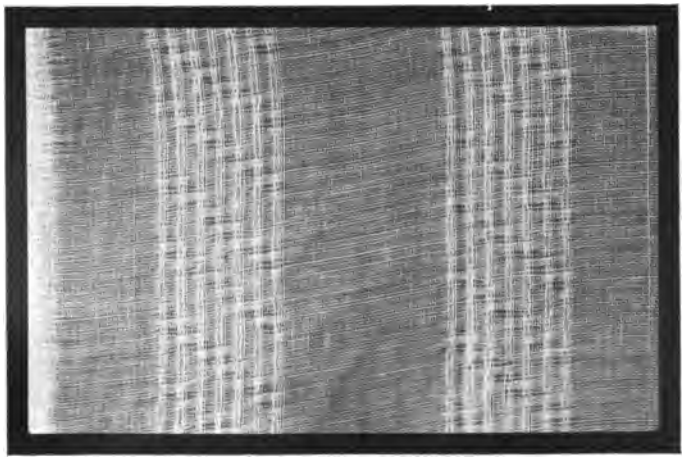
SAMPLE NO. 72.—SATEEN BROCADE.

Jacquard woven, with small filling sateen figures on a warp sateen ground. Finished width, 30 inches.
168 ends and 99 picks per square inch, finished.
Warp yarn, 74s. Filling yarn, 58s.
Weight, 6.73 linear yards (5.61 square yards) per pound, finished.
Bleached, mercerized, and printed in two colors, brown and purple.



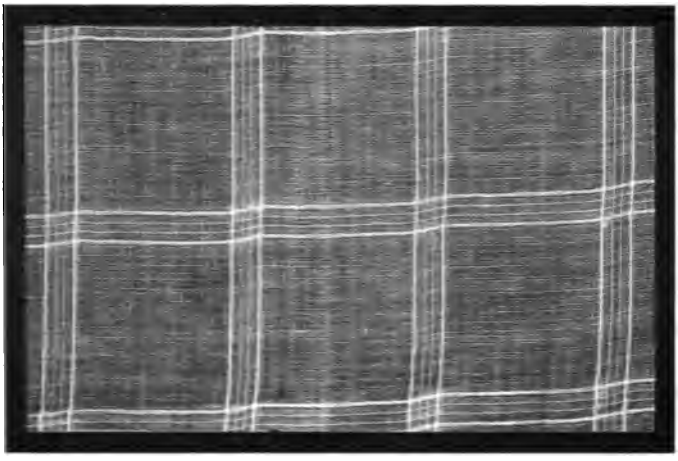
SAMPLE NO. 73.—FANCY PIQUÉ SHIRTING.

Dobby woven (7-harness) on box loom. Finished width, 36 inches.
221 ends and 248 picks per square inch, finished.
Warp yarn, 150/2 and 70s face, 62/2 and 54/2 back. Filling yarn, 152s face, 68s back.
Weight, 3.23 linear yards (3.23 square yards) per pound, finished.
Bleached, mercerized.



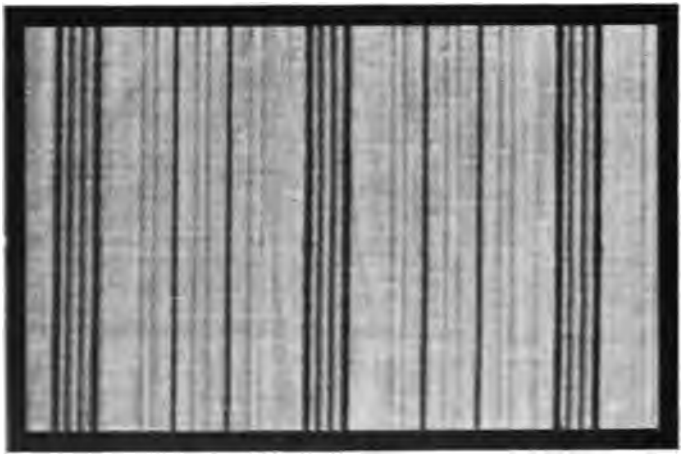
SAMPLE NO. 74.—THREAD-STRIPE ORGANDY.

Dobby woven (9-harness). Finished width, 44 inches.
90 ends and 68 picks per square inch, finished.
Warp yarn, 109s and 39/2. Filling yarn, 147s.
Weight, 10.91 linear yards (13.33 square yards) per pound, finished.
Bleached, organdy finish.



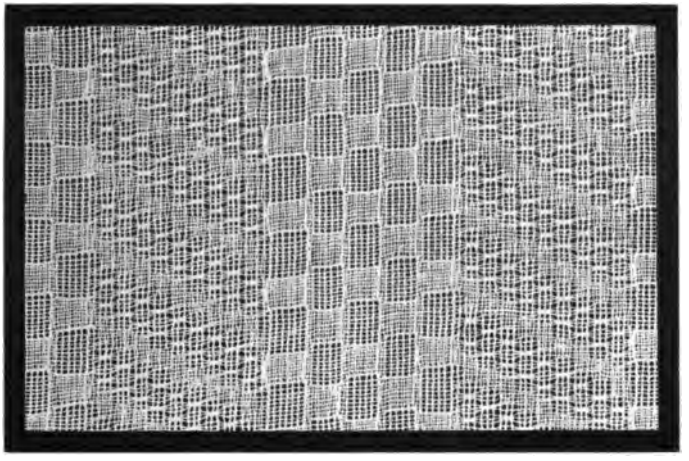
SAMPLE NO. 75.—TRANSPARENT ORGANDY CHECK.

Woven on plain or on dobby loom (4-harness) without boxes. Finished width, 37½ inches.
97 ends and 91 picks per square inch, finished.
Warp yarn, 104s and 104 3, warp cords. Filling yarn, 140s.
Weight, 12.80 linear yards (13.33 square yards) per pound, finished.
Bleached, organdy finish.



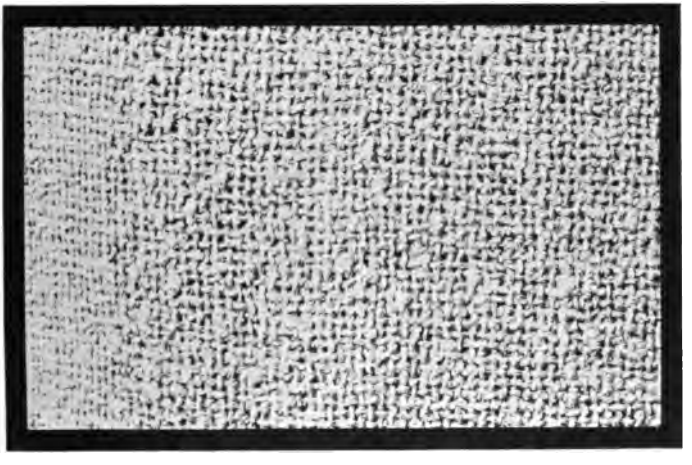
SAMPLE NO. 76. RUSSIAN-CORD SHIRTING.

Plain woven ground with leno covered cords. Finished width, 32 inches.
101 ends and 85 picks per square inch, finished.
Warp yarn, 44s dyed, 44s bleached, cord base, 40 2 dyed and 36 2 dyed; leno whip thread, 76 2 dyed. Filling yarn, 60s bleached.
Weight, 5.89 linear yards (5.24 square yards) per pound, finished.
White, tan, brown, and blue warp, white filling.



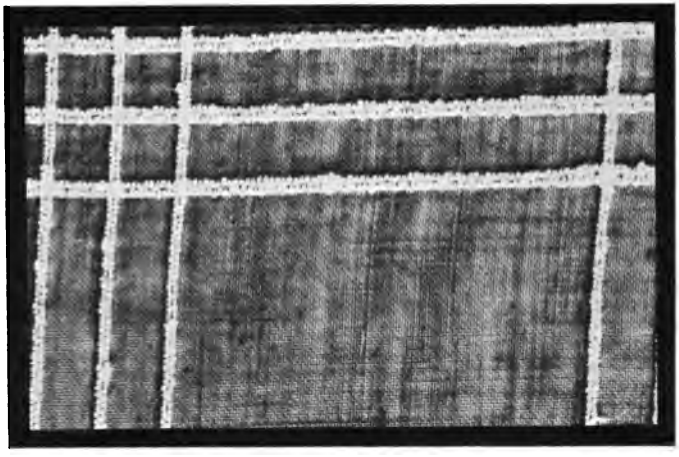
SAMPLE NO. 77.—FANCY LENO VOILE.

Dobby and leno woven. Finished width, 42 inches.
64 ends and 52 picks per square inch, finished.
Warp yarn, 111/2, bleached, 111/2, dyed. Filling yarn, 102/2 bleached.
Weight, 7.62 linear yards (8.89 square yards) per pound, finished.
White warp with blue stripes; white filling.



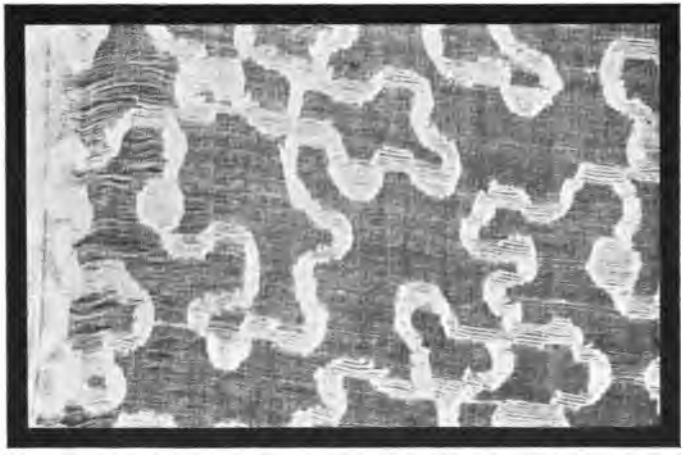
SAMPLE NO. 78.—RATINÉ OR SPONGE CLOTH.

Plain woven. Finished width, 39 inches.
18 ends and 18 picks per square inch, finished.
Novelty yarn composed of 28/2, 14s, and 28s twisted together, in both warp and filling.
Weight, 2.17 linear yards (2.35 square yards) per pound, finished.
Piece-dyed rose.



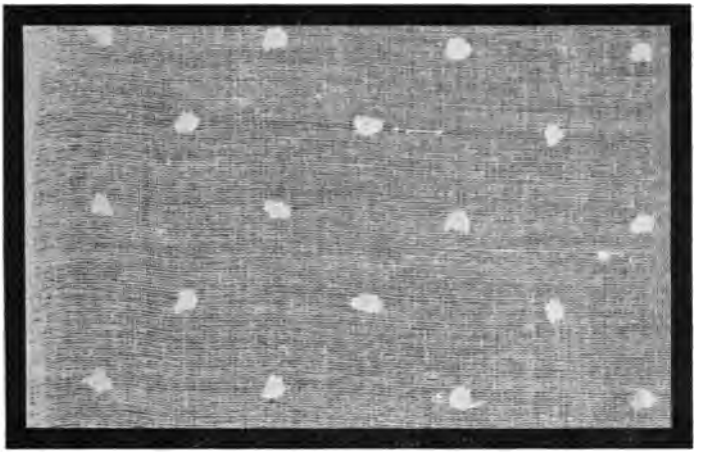
SAMPLE NO. 79.—FANCY NOVELTY VOILE.

Plain woven on box loom. Finished width, 42 inches.
66 ends and 62 picks per square inch, finished.
Warp yarn, 114/2, hard twisted, dyed; 30/4, novelty yarn, bleached. Filling yarn, 134/2, hard twisted, dyed; 30/4 novelty yarn, bleached.
Weight, 6.47 linear yards (7.55 square yards) per pound, finished.
Red voile yarn, and white novelty yarn, in both warp and filling.



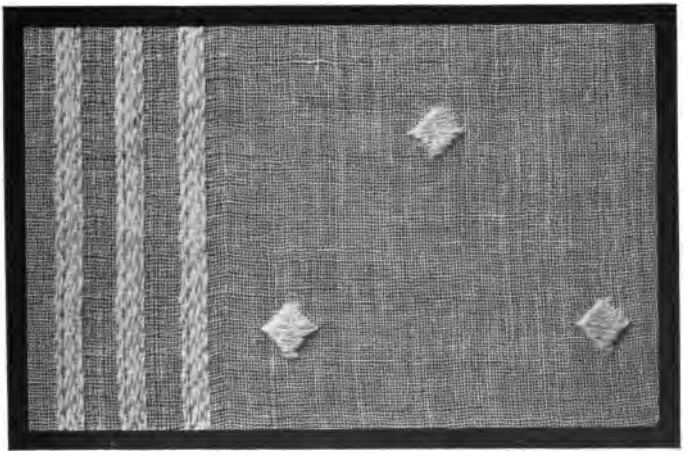
SAMPLE NO. 80.—JACQUARD CLIPPED FANCY.

Jacquard woven. Finished width, 46 inches.
80 ends and 140 picks per square inch, finished.
Warp yarn, 104s. Filling yarn, 115s, with 30s (estimated) in clipped figures.
Weight, 9.27 linear yards (11.85 square yards) per pound, finished.
Clipped, bleached, and starched.



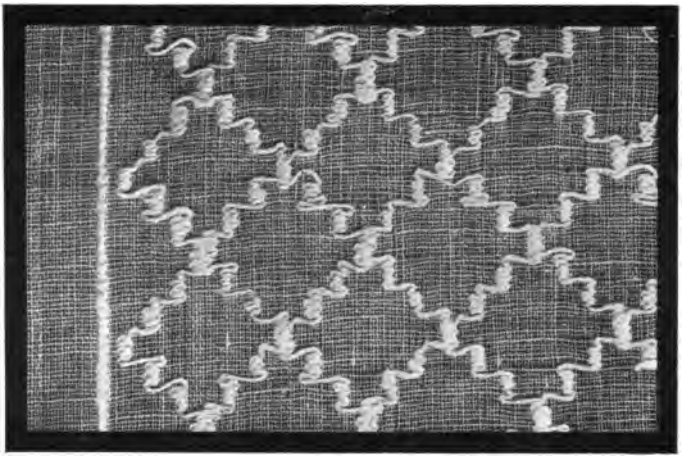
SAMPLE NO. 81.—CLIPPED SPOT LAWN.

Dobby woven (10-harness) on box loom. Finished width, 45½ inches.
82 ends and 79 picks per square inch, finished.
Warp yarn, 98s. Filling yarn, 138s and 20s (estimated).
Weight, 12.66 linear yards (16 square yards) per pound, finished.
Clipped, bleached, and starched.



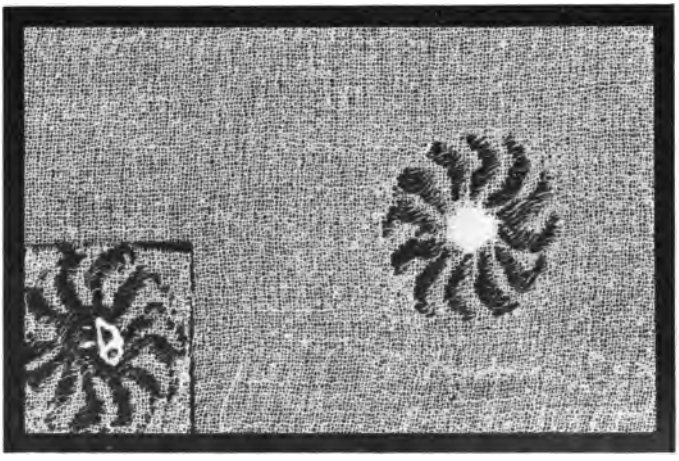
SAMPLE NO. 82.—FANCY SWIVEL VOILE.

Plain woven ground with dobby stripes and swivel figures.
Finished width, 38 inches.
61 ends and 62 picks per square inch, finished.
Warp yarn, 74/2, bleached, 42/3, dyed. Filling ground yarn, 128/2 bleached.
Swivel yarn, 60/3 (estimated), mercerized and dyed.
Weight, 8.19 linear yards (8.65 square yards) per pound, finished.
Blue and white warp. White filling with blue swivel figure. Clipped.



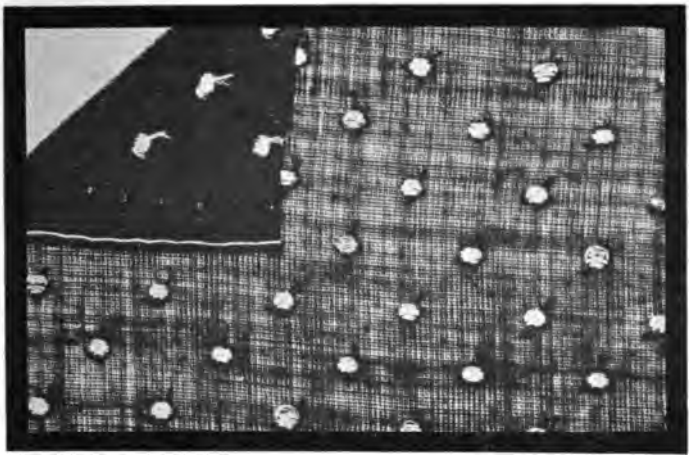
SAMPLE NO. 83.—TWO-FRAME LAPPET.

Plain woven ground with lappet figuring. Finished width, 38 inches.
59 ends and 43 picks per square inch, finished.
Warp ground yarn, 58s, 30/5 cord, 30/3 lappet. Filling yarn, 71s bleached.
Weight, 10.11 linear yards (10.67 square yards) per pound, finished.
Bleached. Printed in olive and blue.



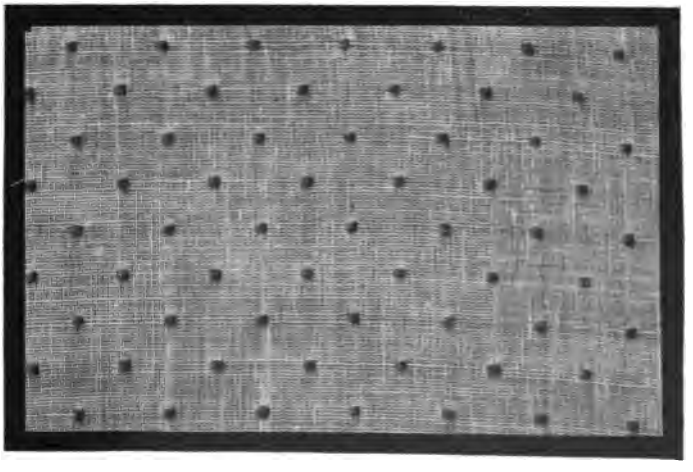
SAMPLE NO. 84.—PLUMETIS CRÊPE.

Plain woven ground with lappet and swivel figures. Finished width, 39 inches.
58 ends and 52 picks per square inch, finished.
Warp ground yarn, 103/2, hard twisted, bleached. Lappet yarn, 40/2 (estimated), bleached, mercerized. Filling ground yarn, 59s hard twisted, bleached; swivel yarn, 40/2 (estimated), mercerized and dyed.
Weight, 7.03 linear yards (7.61 square yards) per pound, finished.
Bleached ground with white lappet and brown swivel threads. Clipped.



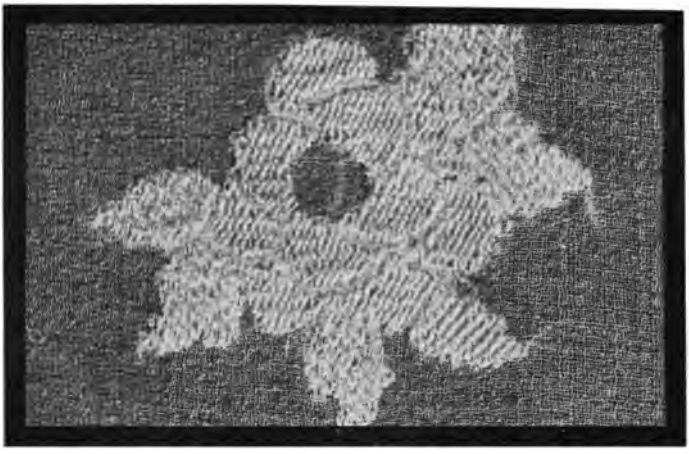
SAMPLE NO. 85.—DOTTED SWISS.

Plain woven ground with swivel dots. Finished width, 31½ inches.
79 ends and 59 picks per square inch, finished.
Warp yarn, 64s, dyed. Filling ground yarn, 55s, dyed. Swivel yarn, 40s (estimated), mercerized and dyed.
Weight, 11.09 linear yards (9.70 square yards) per pound, finished.
Blue warp. Blue filling with red swivel dots. Clipped.



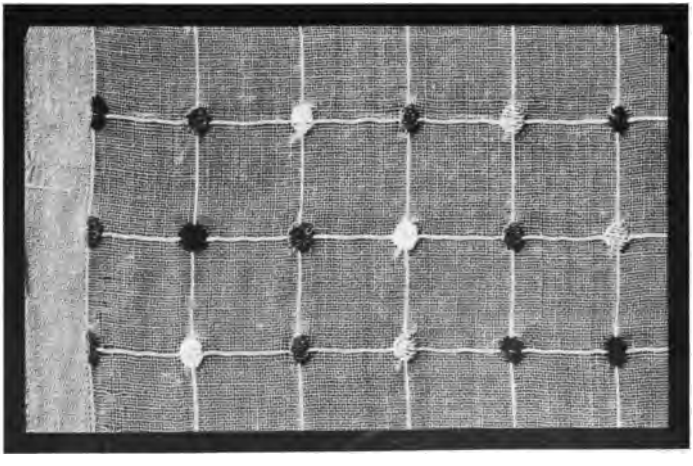
SAMPLE NO. 86.—DOTTED SWISS.

Plain woven ground with swivel dots. Finished width, 31½ inches.
82 ends and 60 picks per square inch, finished.
Warp yarn, 63s, bleached. Filling ground yarn, 90s, bleached. Swivel yarn, 70s (estimated), mercerized and dyed.
Weight, 12.62 linear yards (11.04 square yards) per pound, finished.
Bleached warp. Bleached filling with blue swivel dots. Clipped.



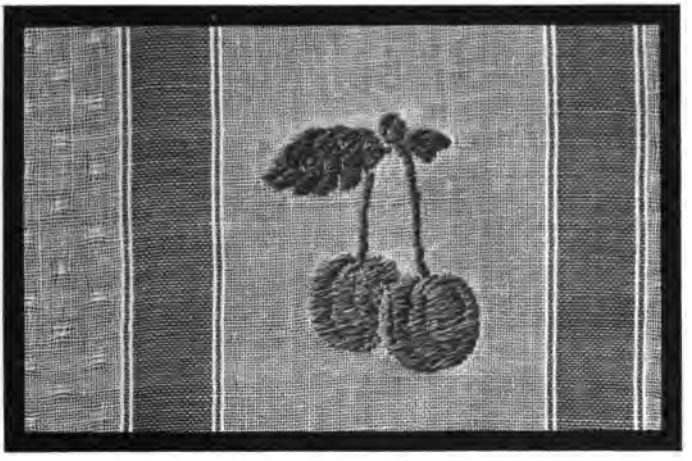
SAMPLE NO. 87.—PLUMETIS CRÊPE.

Plain woven ground with swivel figure. Finished width, 39 inches.
59 ends and 54 picks per square inch, finished.
Warp yarn, 101/2, hard twisted. Filling ground yarn, 93/2, hard twisted. Swivel yarn, 18/2, bleached and mercerized.
Weight, 6.51 linear yards (7.05 square yards) per pound, finished.
Clipped and bleached.



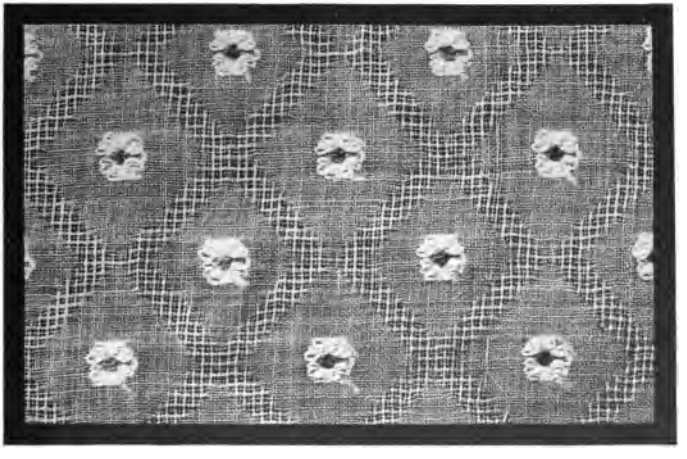
SAMPLE NO. 88.—FANCY SWIVEL VOILE.

Plain woven ground with swivel dots in six colors. Finished width, 41 inches.
73 ends and 67 picks per square inch, finished.
Warp yarns, 132/2, dyed, 132/2, bleached. Filling ground yarn, 136/2 bleached. Swivel yarn, 30/2 (estimated), mercerized and dyed.
Weight, 7.02 linear yards (8.02 square yards) per pound, finished.
Blue and white warp. White filling, with red, green, black, violet, yellow, and blue swivel threads. Clipped.



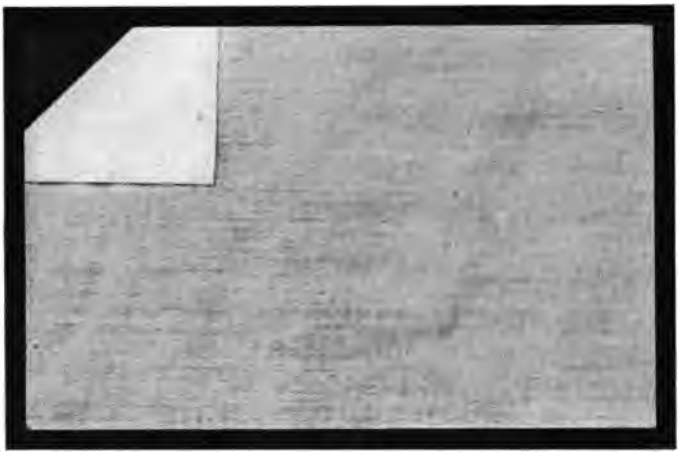
SAMPLE NO. 89.—FANCY SWIVEL VOILE.

Fancy ground with swivel figures. Finished width, 41 inches.
70 ends and 60 picks per square inch, finished.
Warp yarn, 138/2 bleached, 138/2 dyed. Filling yarn, 120/2 bleached. Swivel yarn, 40/3 (estimated) mercerized, and dyed.
Weight, 7.80 linear yards (8.88 square yards) per pound, finished.
Red and white warp, white filling with salmon and green swivel threads. Clipped.



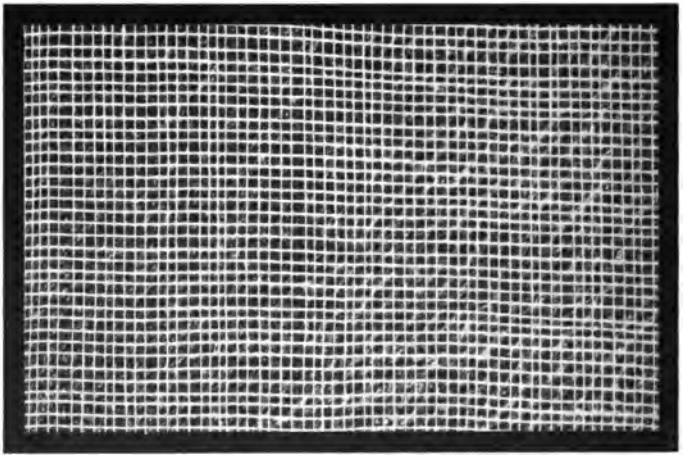
SAMPLE NO. 90 —FANCY SWIVEL AND LAPPET.

Fancy ground with swivel figures. Finished width, 39 inches.
93 ends and 75 picks per square inch, finished.
Warp yarn, 101s, bleached, mercerized. Lappet yarn, 40/3 (estimated), mercerized and dyed. Filling yarn, 134s, bleached. Swivel yarn, 40/3 (estimated), bleached and mercerized.
Weight, 13.43 linear yards (14.55 square yards) per pound, finished.
White warp and yellow lappet yarn; white filling and white swivel yarn. Clipped.



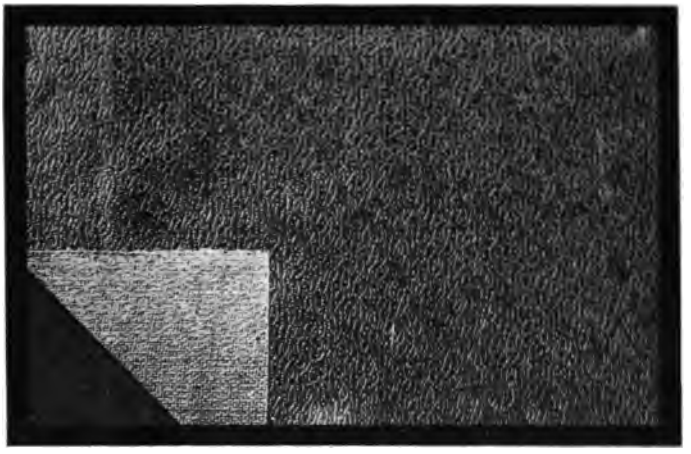
SAMPLE NO. 91.—TRACING CLOTH.

Plain woven. Finished width, 37 inches.
87 ends and 86 picks per square inch, finished.
Warp yarn, 65s. Filling yarn, 83s.
Weight, 5.98 linear yards (6.15 square yards) per pound, finished.
Bleached, coated, and glazed.



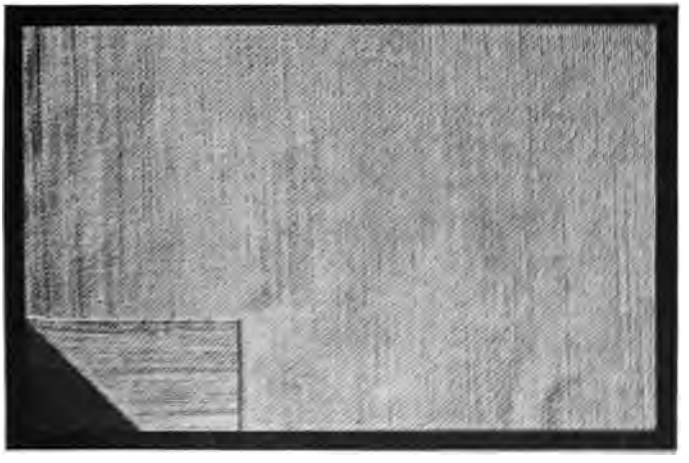
SAMPLE NO. 92.—NEAR GLASS.

Plain woven. Finished width, 54 inches.
19 ends and 18 picks per square inch, finished.
Warp yarn, 72s. Filling yarn, 60s.
Weight, 15.26 linear yards (22.89 square yards) per pound, finished.
Bleached and coated.



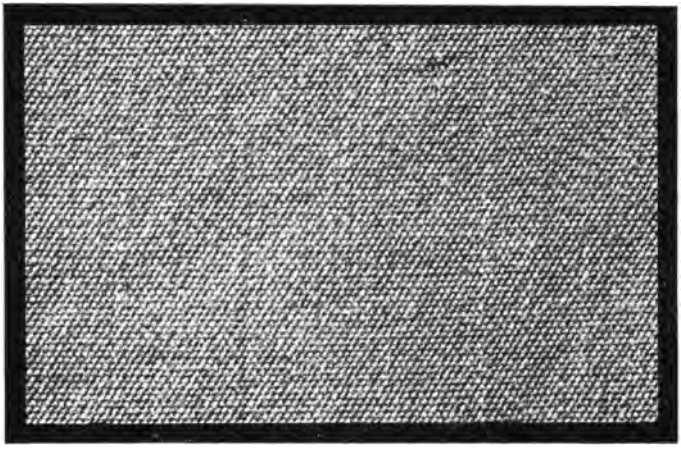
SAMPLE NO. 93.—BOOK CLOTH.

Plain woven. Finished width, 40 inches.
66 ends and 56 picks per square inch, finished.
Warp yarn, 34s. Filling yarn, 35s.
Weight, 3.79 linear yards (4.21 square yards) per pound, finished.
Piece-dyed, coated, and embossed.



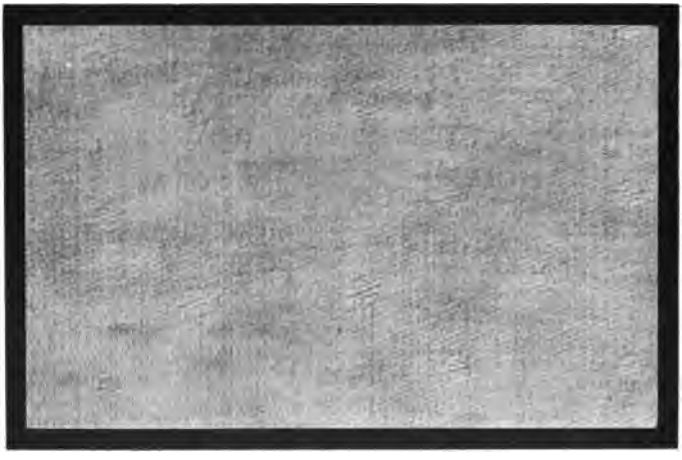
SAMPLE 94.—WINDOW HOLLAND.

Plain woven. Finished width, 48 inches.
67 ends and 55 picks per square inch, finished.
Warp yarn, 22s. Filling yarn, 24s.
Weight, 2.15 linear yards, 2.47 square yards, per pound, finished.
Piece-dyed, lined, beetled, and glazed.



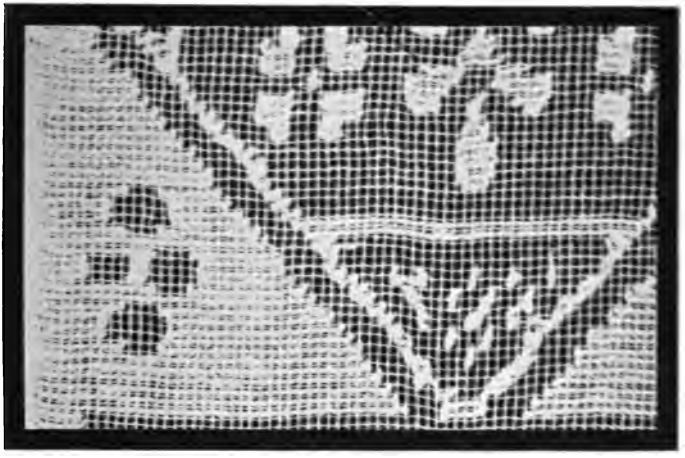
SAMPLE NO. 95.—AUTO TOP CLOTH (WATERPROOF).

Plain woven. Finished width, 60 inches.
54 ends and 32 picks per square inch, finished.
Warp yarn, 12/3, grandrelle. Filling yarn, 12/2, dyed
Weight, 0.63 linear yard (1.05 square yards) per pound, finished.
Grey tint drab warp, grey tint filling. Waterproof, by reason of close weave.



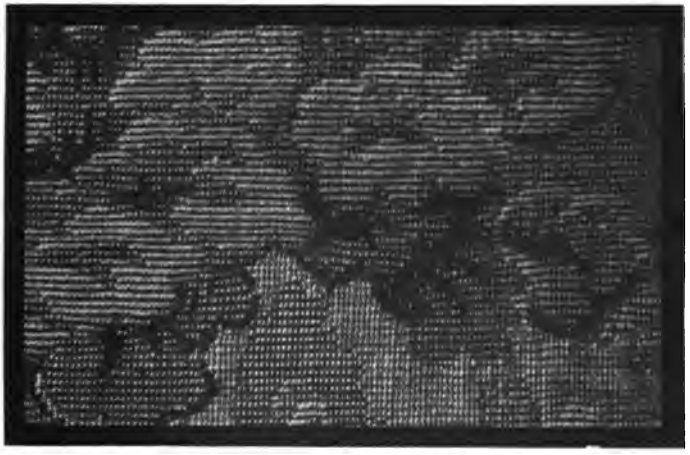
SAMPLE NO. 96.—COTTON TABLE DAMASK.

Jacquard woven, with filling-sateen figures on warp-sateen ground. Finished width, 36 inches.
73 ends and 80 picks per square inch, finished.
Warp yarn, 25s. Filling yarn, 26s.
Weight, 3.75 linear yards (3.75 square yards) per pound, finished.
Bleached, starched, and calendered.



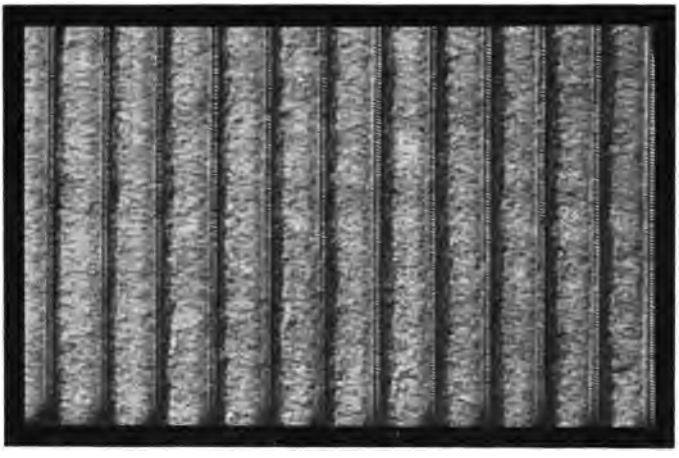
SAMPLE NO. 97.—MADRAS MUSLIN.

Leno ground with Jacquard woven figures. Finished width, 40 inches.
42 ends and 41 picks per square inch, finished.
Warp yarn, 68s. Filling yarn, 58s, with 10s in clipped figures.
Weight, 10.29 linear yards (11.43 square yards) per pound, finished.
Clipped and bleached.



SAMPLE NO. 98.—COTTON TAPESTRY.

Jacquard woven double cloth. Finished width, 50 inches.
139 ends and 72 picks per square inch, finished.
Warp yarn, 41/2 dyed. Filling yarn, 80s, dyed, 5s, dyed.
Weight, 0.95 linear yard (1.32 square yards) per pound, finished.
Green, olive green, blue, brown, red, and salmon warp. Black and grey filling.



SAMPLE NO. 99.—CORDUROY.

Filling-pile weave, plain back. Finished width, 28½ inches.
42 ends and 232 picks per square inch, finished.
Warp yarn, 16/2. Filling yarn, 23s, pile yarn, 23s (estimated).
Weight, 1.39 linear yards (1.10 square yards) per pound, finished.
Cut and piece-dyed silver grey.

SAMPLE NO. 100.—VELVETEEN.

Filling-pile weave, twilled back. Finished width, 27 inches.
84 ends and 156 picks per square inch, finished.
Warp yarn, 37s. Filling yarn, 50s; pile yarn, 50s (estimated).
Weight, 2.95 linear yards (2.21 square yards) per pound, finished.
Cut and piece-dyed black.

NOTE

This is one of a series of Tariff Information Surveys prepared by the United States Tariff Commission. These surveys deal with the commodities provided for by the tariff act in force at the time of their preparation.

When articles or commodities are covered by two or more paragraphs of the tariff act, they are sometimes combined in one survey. This is done only when similarity and industrial relationship are sufficient to justify a joint treatment. When one grade of an article or commodity is dutiable and another grade is on the free list, the entire treatment is effected under the dutiable paragraph.

The commission has issued as a separate pamphlet an index to all its publications. This index lists in alphabetical order the articles or commodities treated in any commission publication.

In the preparation of this survey the commission had the services of R. E. K. Peterson, of the textile division of the commission's staff, and of others.

STATISTICAL TABLES

Page

1. Nominal standard and average count of yarn used by representative manufacturers in the United States for principal cotton threads in standard sizes 6
2. System of numbering mercerized cotton thread, "ounce goods" 7
3. Domestic production of cotton thread, 1890–1925 22
4. Domestic exports of cotton sewing thread and crochet, darning, and embroidery cottons, 1918–1926 24
5. Domestic exports of cotton sewing thread to principal countries, 1922–1926 25
6. Domestic exports of crochet, darning, and embroidery cottons to principal countries, 1922–1926 26
7. Total domestic exports of cotton sewing thread and handwork cottons to principal countries, 1922–1926 26
8. Exports of cotton sewing thread from the United Kingdom, 1889–1926 30
9. Volume of exports of principal foreign countries of cotton sewing thread and cotton yarns for the retail trade, 1913, 1920–1926 32
10. Volume of imports of principal foreign countries of sewing thread and cotton yarns for the retail trade, 1913, 1920–1926 33
11. Total imports for consumption and revenue of cotton sewing thread and cottons for handwork, 1891–1926 35

11a. Imports for consumption and revenue of cotton sewing thread, 1922–1926 37

11b. Imports for consumption and revenue of crochet, darning, embroidery, and knitting cottons, 1922–1926 37

12. General imports of cotton sewing thread and handwork cottons, by countries, 1918–1926 39

12a. Proportion of total imports of cotton sewing thread and handwork cottons obtained from principal countries, 1918–1926 40

13. Relation of imports and domestic production of cotton sewing thread, 1923 and 1925 41
14. Comparison of value of imports and exports of cotton sewing thread, and crochet, darning, and embroidery cottons, 1919–1926 42
15. Average annual wholesale prices, actual and relative, of cotton thread 6-cord, 200-yard spools, J. & P. Coats, compared with annual all-commodities price index, 1890–1926 43
16. Monthly wholesale prices of cotton thread, 6-cord, 200-yard spools J. & P. Coats, 1890–1926 43
17. Wholesale and retail prices in the United States in 1925 of typical imports of handwork cottons of Dollfus-Mieg et Cie, Mulhouse, France 46
18. Wholesale and retail prices in 1925 of domestic handwork cottons, J. & P. Coats' and Clark's O. N. T. brands, competitive with D. M. C. yarns 48
19. Wholesale and retail prices in 1925 of handwork cottons of the American Thread Co. competitive with D. M. C. yarns 50
20. Total imports for consumption of cotton sewing thread and cottons for handwork under each of the last six tariff acts 56
21. Annual average quantity and value of imports of thread and handwork cottons and duty collected under last six tariff acts, October 6, 1890, to December 31, 1926 56
22. Proportions of total imports of cotton sewing thread and handwork cottons assessed at the specific, minimum ad valorem, or maximum ad valorem duty, 1922–1926 58
23. Imports for consumption under act of 1922 of cotton sewing thread and cottons for handwork classified by rates of duty 58

23a. Imports for consumption under act of 1922 of cotton sewing thread classified by rates of duty 58

23b. Imports for consumption under act of 1922 of handwork cottons classified by rates of duty 59

24. Average unit values per 100 yards of imports for consumption of cotton sewing thread and handwork cottons under act of 1922 59
25. Comparison of tariff rates on 6-cord cotton sewing thread and yarn used in its manufacture 60

Page
26. Comparison of average invoice price and duty on 6-cord cotton sewing thread and yarn used in its manufacture 61

COTTON SEWING THREAD AND COTTONS FOR HANDWORK

INTRODUCTION

The cotton-thread industry has two distinct branches, each having a more or less specialized field and a highly diversified range of products. The section of greatest importance produces thread known as manufacturers' thread for use in industry; the other, so-called domestic thread, this term being used to include not only thread for home sewing by hand or machine but also darning, knitting, and art needlework cottons. Although a few of the larger mills make both kinds, most of the mills in the United States confine their production to manufacturers' thread. Census reports show production of "cotton thread" amounting to 23,275,618 pounds in 1921, 31,645,537 pounds in 1923, and 37,585,368 pounds (valued at $59,875,776) in 1925. The Census data include all cotton sewing thread for either manufacturers' or household use, but do not include cottons for handwork—these softer spun threads being included without separate enumeration with cotton yarn—so that the total output of the industry is greater than that shown by the Bureau of the Census.

Considering its historic upbuilding, it is interesting to note that the cotton-thread industry in this country was energized, just as were some of the early railroad enterprises, by the influx of foreign capital. The investment of foreign capital in this branch of domestic industry began during the Civil War period when, because of tariff increases, the Clark Thread Co., of Paisley, Scotland, established a branch in New Jersey, and J. & P. Coats, also of Paisley, took over a domestic plant in Rhode Island. Two other British companies subsequently built plants in this country but were absorbed by the Clark Thread Co. which in turn was itself consolidated with J. & P. Coats in 1896. The Coats concern of Paisley continued to expand its international connections, establishing mills in almost every country of Europe, as well as in Canada, Mexico, Brazil, and Japan.

Another large British company, the English Sewing Cotton Co., of Manchester, England, which had been formed by the merger of 14 thread companies in Great Britain, including a subordinate concern in France and one in Canada, entered the American field in 1898. It purchased practically all the common stock of the American Thread Co., organized by the fusion of 14 domestic thread manufacturers.

Concentration of production is an outstanding feature of the "domestic" or household branch of the cotton-thread industry in the United States. In fact, in the manufacture of spool thread and

handwork cottons for household use there is little small-scale production and there are only a few producers. About nine-tenths of the American output of domestic thread and handwork cottons is made by three large companies which overshadow all the other concerns in size.

In manufacturers' thread, on the other hand, production is diffused among a large number of sharply competing mills. In this branch, the most important in the industry, the three large-scale companies are estimated to produce about 45 per cent of the American supply; a large part of this quota is the output of the American Thread Co., as the other two, the Coats and Clark units, specialize for the most part in domestic thread and handwork cottons. The remaining 55 per cent of the production of manufacturers' thread is distributed among 150 or more medium and small-sized mills and jobbers.

The three large companies and two smaller concerns are integrated plants and conduct the entire cycle of manufacturing processes from the raw cotton to the finished thread. Virtually all of the moderate-sized thread factories, mostly located in New England, start with the grey yarn which they purchase from spinning mills specializing in so-called thread yarns, and carry their operations through the doubling, twisting, dyeing, bleaching, finishing, and putting-up processes. The majority of the small mills which are centralized in the metropolitan area of New York have the conversion processes done for them on commission by mills specializing in the various processes, and engage only in assembling, spooling, and marketing the finished thread. As they sell their goods under their own trade-marked brands, these small concerns enter into price competition with manufacturers who conduct all or most of the thread-making operations in their own plants.

Imports of sewing thread in recent years have tended to diminish and amount to a very small percentage of the total domestic production. They are largely supplemental, as the two large thread concerns abroad do not market any significant part of their exportable surplus in this country.

The branch of the industry producing cottons for handwork is the one most seriously affected by foreign competition, which is heaviest from France. During the three years, 1923–1925, imports of French origin averaged about 70 per cent of the total quantity and 85 per cent of the total value of all the imports under paragraph 902 of the act of 1922; in 1926 the proportions were approximately 60 and 80 per cent, respectively. French handwork cottons have been held in high repute for fastness of dye and high luster, and prior to the war were generally considered superior to the domestic. The curtailment of imports during the period of hostilities, however, stimulated the American manufacturers to expand their output and improve the quality, with the result that domestic handwork cottons now compare favorably with the imported and are steadily growing in popular estimation. The domestic producers, moreover, have a distinct advantage in their proximity to United States markets, which enables them to supply consumers on short notice. The price differential in favor of American handwork cottons and the ready response of manufacturers to market demands both operate to aid domestic producers in the face of the heavy competition from France.

The United States exports of sewing thread are considerably smaller in value than imports. In late years they have been on the decline, dropping from 1,653,184 pounds in 1922 to 960,454 pounds in 1925, but rising in 1926 to 1,299,269 pounds. The three principal thread manufacturers in this country cater primarily to home-market demand. American producers of thread who had developed an export business during the war when European production was at a low ebb now find it difficult to compete in the world markets against the two chief British thread manufacturers, J. & P. Coats (Ltd.) and the English Sewing Cotton Co., 80 per cent of whose production in the United Kingdom is destined for the export trade. With their wide commercial and industrial affiliations of an international character, these leading British companies virtually dominate the cotton sewing-thread production and trade of the world. The competitive strength of the British thread industry in international commerce is evidenced by the exports from Great Britain, which attained a record of 34,695,400 pounds in 1900 and averaged during the five years 1922–1926 about 18,000,000 pounds a year.

Domestic exports of crochet, darning, and embroidery cottons amounting to 291,456 pounds in 1922, declined to 97,701 pounds in 1925, and recovered to 123,400 pounds in 1926. Exporters of American-made handwork cottons find considerable difficulty in competing against the trade prestige of long-established European brands, particularly the French.

COTTON SEWING THREAD AND COTTONS FOR HANDWORK

GENERAL INFORMATION

TARIFF ACT OF SEPTEMBER 21, 1922

PAR. 902. Cotton sewing thread, one-half of 1 cent per hundred yards; crochet, darning, embroidery, and knitting cottons, put up for handwork, in lengths not exceeding eight hundred and forty yards, one-half of 1 cent per hundred yards: *Provided*, That none of the foregoing shall pay a less rate of duty than 20 nor more than 35 per centum ad valorem. In no case shall the duty be assessed on a less number of yards than is marked on the goods as imported.

SCOPE OF THE INDUSTRY

The thread industry has two distinct branches, namely, "domestic" or household threads and manufacturers' threads. The designation "domestic threads" is an established trade term covering all the products sold through the retail dealer to the ultimate consumer for hand or machine sewing and art needlecraft. This branch includes not only sewing thread but also darning, mending, knitting, crocheting, tatting, and embroidery cottons.

The production of manufacturers' threads is the most important branch of the thread industry. The strides that have taken place in industry through the invention of sewing machines of highly specialized construction have brought about a great development in the factory production of articles formerly made in the home or by the small-shop artisan and craftsman. This development has resulted in a coordinate expansion in the thread industry to supply manufacturers with threads strong enough to withstand the complicated processes of stitching under the heavy tension of the high-speed, motor-driven factory sewing machines and suitable for the many types of machines and for different textile fibers and materials. Besides the great amount of general-utility thread employed in the manufacture of apparel and house furnishings, special threads are now prepared for use in making shoes, saddles, luggage, gloves, gas mantles, baseballs, automobile tops, upholstery, carpets, awnings, sails, flags, umbrellas, mail bags, overalls, corsets, straw hats, etc., and for the floral and the bookbinding trades. In addition there are also produced threads adaptable to particular operations such as buttonholing, serging, and blindstitching.

As a result of the various demands of the trades, as well as the needs of the home seamstress, the manufacture of thread has become a specialized and complex industry involving the production of thousands of articles differing with regard to size, construction, twist, color, finish, put-up and yardage, quality, and brand.

COTTON SEWING THREAD

Definition.—Cotton sewing thread may be defined as a smooth, evenly spun, hard-twisted, ply or cable yarn, treated by special finishing processes to make it resistant to abrasion in its passage through the eye of a needle and through materials in seaming and stitching operations.

Construction.—Sewing threads for both domestic and manufacturers' use may be either plain laid or cable laid. Special threads for the shoe industry may also be braided. In plain laid, sometimes called "straight-doubled" threads, a number of ends of single yarns are by one operation twisted into a ply yarn. In cabling, on the other hand, there are two twisting operations, the first making the ply yarn from two or more singles and the second making the cabled yarn or thread from three or more ply yarns. Certain industries demand the cable laid, but threads for ordinary purposes are generally plain laid. The production of cabled threads, except for household use, is on the decline. For home consumption, however, the standard thread is cabled because of the diversified uses to which it is put in both hand and machine sewing. In handwork particularly, since a definite length of thread passes its full length through the cloth at every stitch, the amount of manipulation and wear which the thread undergoes is considerably more than in machine sewing work. Household thread is therefore given the extra doubling to make it hard and compact enough to prevent fraying.

Threads of a braided construction, which were developed during the war for the shoe industry, consist usually of 16 ends or strands of single yarn plaited together on a braiding machine instead of twisted together on a doubling machine. Braiding is employed to avert the stranding difficulties often met with in a thread with an improperly balanced twist when loose riders are picked up by the needle barb in the shoe machine or when the tension of the machinery is so heavy that the twist is backed up by the pressure.

Manufacturers' thread in plain-laid form for general sewing is produced in 2, 3, and 4 cord. The word "cord" is employed in the thread industry to designate the number of single ends composing the thread and is synonymous with the spinners' term "ply," the two words being frequently used interchangeably. For special industries, notably the shoe industry, requiring threads of exceptional strength, the cords range progressively up to 28, both in plain and cable construction. Household thread for hand and machine use is largely a 6-cord cabled product; domestic 3-cord plain-laid threads are for basting and for seaming operations in which security and durability are less essential requisites; a high grade of sewing thread, especially in the mercerized finish, is also now sold in 3-cord for the domestic trade.

Twist.—The direction of the twist in straight-doubled threads is always opposite to that inserted in the spinning of the single yarns from which the thread is made. When the revolutions of the spinning spindle have been toward the right, producing a single yarn with a so-called regular twist, the twisting spindles in the thread doubling operations are turned in the opposite direction, giving a thread with a left or reverse twist. Threads for manufacturing purposes are made with either left or right twist. Some industrial sewing ma-

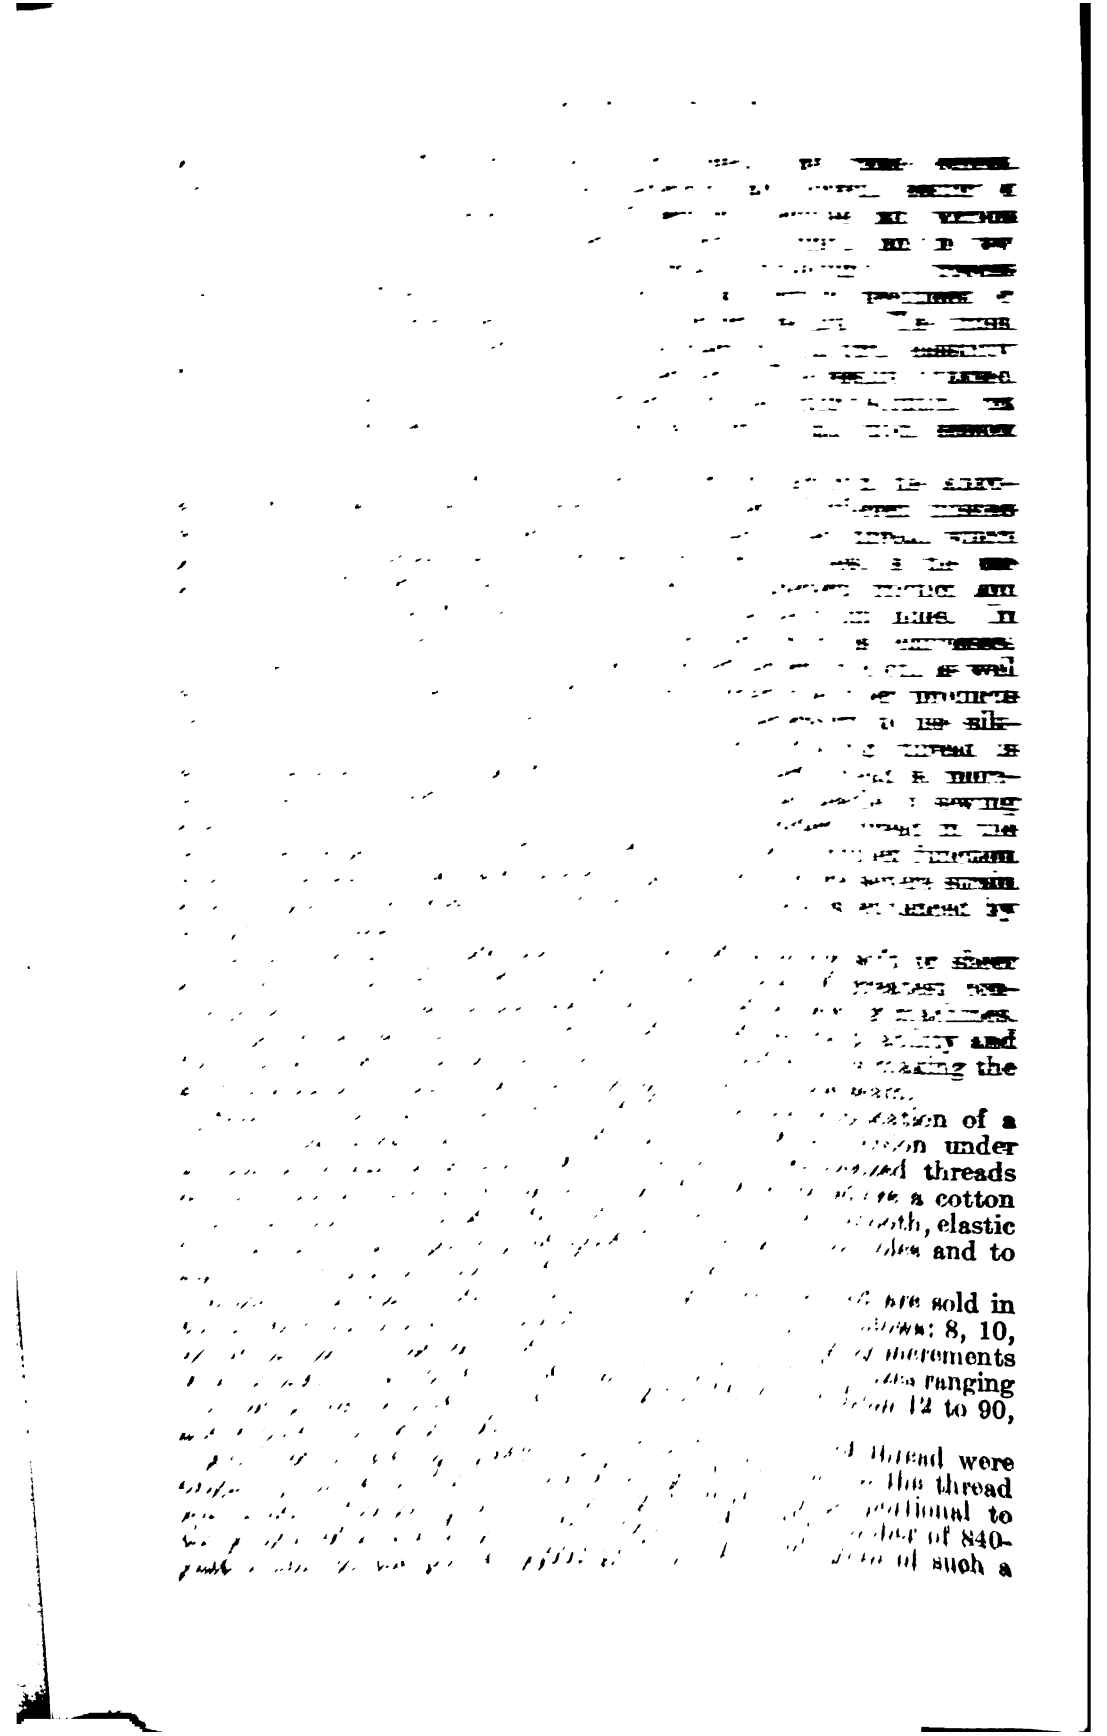
chines require a left twist for the upper or needle thread, when either a left or right twist may be used for the bobbin or looper. Multiple-needle machines often employ a right-twisted thread for one needle or set of needles and a left-twisted thread for another. This requirement necessitates the production of threads of both twists. The bulk demand is for the left twist, which is the standard in the sewing-thread industry, and unless otherwise specified by a consumer this is the twist supplied.

In cabled threads, such as 6-cord household thread, there are three twists, the first imparted in the spinning of the single yarn, the second in the ply, and the third in the cabling. The two methods of inserting the doubling and cabling twists are as follows: (1) Single yarns may be doubled into the ply in the same direction as in spinning, that is, to the right; this is designated "twist on twist." The finishing twist which cables the plied yarns is then inserted directly opposite the two preceding twists, making it regular-regular-reverse, or hawser twist. (2) A 6-cord thread may be made by altering the twist with each doubling, making the twist regular-reverse-regular, or cable twist. This twist is not successfully used for sewing thread, but is employed for the 6-cord crochet cotton known as cordichet or crochet twist. Six-cord sewing thread is made "hawser twist," though ordinarily it is referred to under the broader term "cable twist."

The amount of twist to be inserted in the spinning and in the doubling of the yarns is a technical detail of considerable importance in the production of high-grade thread. The twists must be properly balanced in order to prevent the thread kinking at the eye of the needle. The turns of twist per inch to be inserted in spinning are based on the square root of the yarn number, and the turns of twist to be inserted in doubling are based on the square root of the equivalent yarn number (obtained by dividing the single-yarn number by the ply) times a twist constant. The selection of the correct twist constant is a matter of judgment and involves consideration of various factors such as the length of staple of the raw cotton, the structure of the thread, and the use for which it is intended. In the case of straight-laid sewing thread for general consumption the ply-twist constant is usually about 5½. Using this twist constant, a 3-cord thread made of 30s singles, for instance, would have 5½ times 3.16 (the square root of 10, i. e., 30 divided by 3), or 17.38 turns twist per inch. The ply twist in ordinary 3-cord sewing threads ranges from about 16 to 30 turns per inch.

Finishes.—Threads, other than the natural grey, are made in three standard finishes: (1) soft or dull; (2) "silk," also called polished, hard, or glacé; and (3) mercerized. Between each of these classes are numerous intermediate finishes.

A soft-finished thread is one that has been treated with a sufficient amount of softening ingredients to give it slipping qualities and to overcome the harshness consequent upon the removal of the natural oils from the cotton in the bleaching and dyeing process. To obtain a silk-finished thread, a special dressing consisting of a combination of ingredients such as beeswax, gum arabic, paraffin, starch, and white soap, is applied to lay the fuzzy projecting fibers into the body of the thread. The polishing process works the ingredients into the thread and gives luster and smoothness. Formulas for sizing com-



size that a hank of 840 yards weighs 1 pound, or a unit-testing section of 120 yards (one-seventh of a hank) weighs 1,000 grains, is designated as No. 1. If 120 yards weigh 500 grains, or two hanks consisting of 1,680 yards weigh a pound, the yarn is No. 2, or one-half the size of No. 1. Thus a unit of 120 yards of single yarn weighing 25 grains would be one-fortieth of the size of a No. 1 yarn and would be called No. 40 yarn. A pound of No. 40 yarn would contain 40 hanks and would therefore run 33,600 yards to the pound (forty times 840). The number or count of any cotton yarn is obtained by weighing a testing skein of 120 yards, called a lea, and dividing the weight in grains into 1,000. For a ply yarn the resultant is multiplied by the number of ends to find the count of the component yarns. The number of yards per pound is determined by multiplying the yarn count by 840 and dividing by the ply.

In the early history of the thread industry 3-cord thread was the first commercial product, and manufacturers numbered it according to the size of the yarn from which it was made. Thus a 3-cord No. 30 thread was made from three strands of 30s single yarn twisted into one. In actual proportions the 30 3-cord thread was equivalent to a single strand of No. 10 yarn, as it would run the same number of yards to the pound. With the introduction and development of other cords or plies of sewing threads, such as 2, 4, and 6 cord thread, the system of numbering was not changed and the 3-cord thread became the standard for all. In order, however, to make the threads of the same ticket number, but of different plies, equivalent in diameter or circumference to the 3-cord, to permit their passage through needles with the same-sized eye, it became the practice to vary the size of the yarn from which the thread was made. As a result, the number of yards to the pound of thread of the same ticket but of different plies remains constant under this system. A 3-cord No. 30 thread, therefore, being made from 30/3 yarn measures 8,400 yards to the pound, and is equivalent to a 10s single yarn. To obtain this same amount of yardage in a 2-cord size 30 thread, two plies of 20s yarn would be employed; in a 4-cord size 30 thread, four plies of 40s; and in a 6-cord thread of the same ticket number six strands of 60s. In this instance the 2-cord, 3-cord, 4-cord, and 6-cord are all labeled with the same ticket No. 30 and are composed of different sizes of yarns, ranging from 20s to 60s, according to the number of ends in the thread. Since all of them measure 8,400 yards to the pound, they all fit the eye of the needle adapted to size 30 3-cord thread.

In ordinary 3-cord sewing thread, from No. 16 to No. 40, the labeled ticket number coincides with the yarn number from which the thread is made. Above size 40 there is a departure in the uniformity of the system, and the numbering is an arbitrary process. Size 50 3-cord thread is made nominally from 45s yarn instead of 50s yarn, size 60 thread from 50s yarn, size 70 thread from 60s yarn, and so on up to 110 ticket size. Above size 50, therefore, and up to size 110, there is a differential of 10 between the ticket size and the yarn number.

Six-cord thread between ticket sizes 16 and 50 is made from yarns twice as fine as the 3-cord bearing the same number. Above size 50 the differential of 10 enters into the numbering of 6-cord as well as 3-cord threads. While a 3-cord thread bearing ticket size 60 would

be made nominally from 50s yarn, the yarn used for a 6-cord thread size 60 would not be exactly double the ticket size, but would be 110s instead of 120s.

Although the system as outlined above is the basis of the nominal standards for the yarn sizes entering into the ticket numbers of thread, individual manufacturers do not strictly adhere to it in practice. The yarn from which the thread is made usually varies several counts below the theoretical standard. This divergence and lack of conformity may be attributed to the difficulty of adhering to the nominal basis because of variations in the constituency of the yarn in the technical processes of manufacture into thread. As the sizes of yarn are based upon the grey, subsequent treatment such as boiling off, bleaching, dyeing, twisting, gassing, and mercerizing not only affect the properties of the yarn but alter the yarn count. To make up for the gains or losses resulting from these various processes, the manufacturers start with a coarser grey yarn than called for, since the grist will come up to that required for the thread in the final product. Because of this permissible deviation from the theoretical standard in the yarn sizes which comprise the ticket numbers for the various plies or grades of thread, the following table is presented to show the average used among various manufacturers of thread in the United States.

TABLE 1.—*Nominal standard and average count of yarn used by representative manufacturers in the United States for principal cotton threads in standard sizes*

Ticket number	3-cord thread		4-cord thread		6-cord thread	
	Average count of natural grey	Nominal standard	Average count of natural grey	Nominal standard	Average count of natural grey	Nominal standard
16	15	16	20	22	30	32
20	18	20	26	27	38	40
24	22	24	30	32	47	48
30	28	30	37	40	57	60
36	33	36	43	45	67	72
40	37	40	47	50	76	80
50	42	45	56	60	96	100
60	47	50	66	70	106	110
70	56	60	76	80	115	120
80	66	70	86	90	125	130

That yarn numbers do not measure up to the theoretical standard is not, therefore, an indication of misrepresentation. It is the necessary result of the technicalities of the industry and the attempt to make the threads of different plies but the same ticket number correspond to the same diameter, in order to permit their passage through the same needle with approximately the same tension.

Numbering of mercerized thread.—Mercerized cotton threads for manufacturers' use in both 2-ply and 3-ply are numbered according to the standard used in numbering silk thread. In this system the variable lengths of silk per ounce are designated arbitrarily by alphabetical letters, ciphers, or series of ciphers, as shown in the following table:

TABLE 2.—*Typical system of numbering mercerized cotton thread ("ounce goods")*

Character	Equivalent ticket number of unmercerized cotton (approximate)	Nominal yarn count from which made	Character	Equivalent ticket number of unmercerized cotton (approximate)	Nominal yarn count from which made
0000	80	70	D	24	20
000	70	60	E	20	16
00	60	50	EE	18	14
0	50	40	F	16	12
A	40	36	FF	12	8
B	36	30	G	10	6
C	30	24			

The nominal yarn counts used by different manufacturers vary, but the insertions in the table above are representative of trade usage.

Numbering of cotton-welt thread.—The sizes of heavy cotton threads used for sewing welts on shoes follow the system employed in the numbering of heavy linen welt threads. The ordinary size of the single bleached linen welt yarn is 19½ lea or 20 lea, and the ticket numbers are based on the number of cords in the thread. A No. 6 linen-welt thread consists of six cords or plies, each being composed of size 19½ lea. The present practice of the cotton-thread manufacturers is to match the diameter of the cotton-welt thread to the linen. In straight-laid thread this is done by using a size 8¼ singles cotton yarn which corresponds approximately to the 19½ lea linen singles. The number of cords in plain-laid cotton-welt thread ranges from 3 to 14, and the various threads are ordered according to the cord. In braided welt thread, on the other hand, the number of cords or ends braided together is constant for all ticket numbers, 16 ends being the general usage. The yarn count of the individual ends, however, is varied to obtain different sizes of the finished welt thread. The ticket numbers applied to the cotton-welt thread correspond to those used for linen thread having the same diameter. A braided cotton-welt thread of ticket size No. 7 is, for instance, made up of cotton yarn of such a size that 16 singles equal in diameter seven strands or cords of linen yarn of size 19½ lea.

Colors.—Manufacturers of cotton thread and art neeedlework cottons follow the colors determined upon by the Textile Color Card Association and are therefore constantly shifting their color range from one season to another. Domestic sewing thread and handwork cottons are made in more than 200 colors, but each manufacturer, however, has a standard assortment of approximately 80 or 90 staple shades. The bulk of the colors are produced in sizes 50, 60, 70, and 80. The color card for manufacturers' threads is somewhat smaller than that for the domestic line, embracing 185 shades in the complete range. About 50 of these are standard shades in steady demand. A fairly large quantity of thread for industrial use is sold in the natural unbleached grey as a bobbin and looper thread in the manufacture of workingmen's garments and for serging operations.

Put-up and yardage.—Prior to the war the standard form of put-up for domestic cotton thread was the 200-yard length wound on small wooden spools. During the war period the quantity per spool was

reduced to 150 yards; the present quantity is 100 yards. The domestic thread is furnished to the retailer in wooden cabinets containing 25 or 50 dozen spools of assorted ticket numbers, in the proportion of about 70 per cent white and 30 per cent black. The size in greatest demand is ticket No. 50, which represents about 40 per cent of the total number of spools in the cabinet. Nos. 40 and 60, the next in demand, comprise approximately 20 and 18 per cent of the total; Nos. 36 and 30 constitute about 5 per cent each; and Nos. 8, 10, 12, 16, 20, and 24 about 2 per cent each of the total. Colored domestic threads are packed in boxes of a dozen spools of one size and color, and in 5 dozen cartons containing 2 spools each of 30 shades or 3 spools each of 20 shades.

Domestic threads are also marketed in 200, 250, 500, and 800 yard spools for basting, millinery, and general sewing, and on 50 and 75 yard spools for special uses such as carpet and button stitching.

Another form of put-up for home consumption is that in the so-called "thread lengths" composed of threads of assorted colors braided together in a flat, ribbonlike band from which the thread may be pulled out as needed.

Manufacturers' thread for ordinary sewing purposes in soft and silk finishes is put up in 500, 1,200, 3,600, 4,800, 6,000, 7,200, 9,600, and 12,000 yard lengths on paper tubes, cones, and wooden spools called jumbo or bull spools. The latter holding the two maximum yardages is the most expensive, owing to the greater winding costs and the high outlays for the white birch wood for the spools. Since the discarded spools are not refilled, the initial cost is not compensated for by repetition of use. They are now being superseded more generally by winding receptacles of papier mâché, which insure better delivery on the sewing machine and greater elasticity. Tubes are a popular form of put-up for silk-finished threads. Cones are most generally employed for soft-finished threads. The thread manufacturer generally follows the dictates of the consumers in the manufacturing trades, who often order a form of put-up in accordance with the customs and traditions of their particular industry, rather than with reference to economy in the thread manufacturers' production program.

Mercerized cotton thread, like silk thread, is known as ounce goods and is put on 1-ounce spools and 2-ounce tubes and also on one-half pound cones or tubes for manufacturing use.

Cabled lock-stitch thread and braided lock-stitch thread for sewing soles to welts in the shoe industry are sold by the pound and are called weight goods or cotton weights.

Another form of put-up for manufacturers is the ready-wound bobbin for sewing machines which require shuttles. First introduced in 1884, these ready-wound bobbins are now produced by four manufacturers in the United States. Because of the necessity of properly fitting the various types of shuttles in different kinds of sewing machines, there are on the market over a dozen styles of ready-wound bobbins and in each type is a full range of sizes, qualities, and colors, indicating again the wide scope of production necessary in the thread industry to meet all demands.

Quality and brands.—The strength, pliability, elasticity, smoothness, and uniformity of cotton sewing thread are the primary criteria of quality, and these characteristics of the thread are dependent on

the length and evenness of the staple or individual fibers in the raw cotton, the uniformity of spinning, the balance of the twist, and the finish applied. There has been no standardization of quality in the thread business, and the consumer is dependent almost entirely on the reputation and reliability of the manufacturer for a satisfactory product.[1] A number of large manufacturers who maintain quality standards in their output have a system of brand names for different classes or qualities of their thread. There are four or five categories of quality known to the consumer under the brand name rather than the class number, the brand standing for standardized merchandise made from a certain type and quality of cotton. The standard 3-cord thread is generally made in all qualities; 2-cord in three; while 4-cord and 6-cord are produced as a rule in only the first quality. There are, however, some limited quantities of second-grade 4-cord on the market. Practically all the qualities or grades of thread are made in the full range of sizes for each cord.

The production of different qualities of thread is the result not only of a desire on the part of the manufacturers to cater to the different purchasing powers of their various customers but of the necessity for different grades of thread for different purposes. As mentioned before, the price and ultimate use of the garment or articles to be sewn, the kind and density of the fabric or material of which it is made, the construction, appearance, and strength of the seam, and the number of plies or thicknesses of material in the seams, the type of stitch employed (shuttle, chain, double locked, overedge, flat seam, etc.), the number of stitches per unit length, and number of rows of stitching per seam are all factors which have a bearing on the quality of the thread to be employed. Different combinations of thread are also required for the needle and for the bobbin or looper in sewing machines. The under thread in the bobbin or looper reaches the fabric with its full strength and in general may, therefore, be of 20 to 25 per cent finer quality than the upper thread and frequently of one less ply. In the formation of the shuttle stitch the needle thread which thrashes through the eye of the needle from 30 to 80 times before passing a given point is impaired at least 18 to 20 per cent by chafing before reaching the stitch. To stand the strain of such heavy friction, the upper thread must be either of a higher grade cotton or heavier in ticket size than the bobbin thread. In the formation of the chain and double-locked stitch the upper thread passes through the eye of the needle only once, and therefore is not chafed; the under thread for stitches of the latter construction is, however, considered to be reinforced at least twofold by being laid in a triple series in the formation of the loops and hence may be from two to three sizes finer than the needle thread. Some manufacturers recommend that the under thread be approximately one-half the size of the top thread of the same quality.

Number of brands.—A directory of cotton-thread brands in the United States, compiled in 1925 by the Cotton Thread Association (Inc.), listed nearly 1,150 trade-marked brands reported by 67

[1] An important development of recent years is the tendency among big users of thread to test their thread purchases as to size, strength, yardage, and quality, instead of relying on the brand or trade-mark and the guaranty of the maker. Some large companies not only disregard the value of established trade-marks entirely, but as a matter of policy insist on buying goods put up plain without brand marks. This materially affects the nature of the thread business, making cotton thread more of a staple commodity than a proprietary article.

companies. As these firms represent less than one-third of the tota number of active producers and miscellaneous distributers, the aggregate number of brands on the market probably amounts to several thousand.

This multiplicity of brands is in some degree the outcome of the position of the jobber in the distribution of the thread. Many so-called thread producers are in reality jobbers acting as converters who purchase yarn from various mills and pass it around among bleachers, dyers, and winders for the various operations necessary in the conversion of yarn to thread. The amount of converting which a jobber handles as a part of his business may vary from mere spooling and labeling to almost all the processes of thread making except the actual spinning of the yarn. The jobber controls the labeling of the thread which he distributes to the retailer or consumer under his own trade-mark.

Localization of demand.—The conservatism of thread consumers and their reluctance to change from any article to which they have become accustomed has brought about localization of demand for particular brands. This is especially true of domestic threads. As a result of this adherence to tradition and custom, the two largest manufacturers of domestic thread, with virtually the same scope of output, have well-defined fields of sales. The large cities of the East have become almost the exclusive market for the products of the one; the small towns of the South and Middle West the sales area for the other.

HANDWORK COTTONS

In addition to the production of sewing thread for hand and machine work, the so-called "domestic" branch of the thread industry includes also yarns known as handwork cottons which are used for darning, mending, knitting, crocheting, tatting, couching, embroidering and general art needle work.

Darning and mending cottons.—Darning and mending cottons are soft-spun "grouped" yarns consisting of 2, 3, or 4 ends of 2-ply yarn laid parallel in a process of multiple winding. Although the terms darning and mending are synonymous and interchangeable in the trade, the word "darning" is more frequently used to designate the plain, unmercerized cottons for coarse work. Mending cottons, on the other hand, generally denote the better grade, higher priced, mercerized variety, suitable for fine repair work on lisle and silk hosiery, and adapted also to embroidery as well as for padding in the embroidery of monograms or conventional motifs.

Darning cotton usually consists of 3 or 4 ends, while mending cotton, as a rule, is composed of 2 or 3 ends. Plain, unmercerized, darning cotton is made from 24s to 30s 2-ply yarns, whereas mercerized mending cotton is generally made from 34s to 40s 2-ply yarns.

Papier-mâché spools, balls, or cards carrying various yardages and a varying number of ends are the popular forms of put-up for darning and mending cottons. One brand is wound on cubes, a patented form of put-up. Probably the item of greatest consumption in the plain darning cotton is the 45-yard put-up consisting of four ends of 2-ply yarn. It also is produced in other forms such as 30-yard and 45-yard put-ups with 2 ends of 2-ply; 30-yard, 3 ends of 2-ply; 25-yard, 4 ends of 2-ply. In mercerized mending cottons the

pre-war put-ups were 30 and 36 yards, 4 ends; at present they are manufactured in the 2-end and 3-end form running 45, 50, 75, and 100 yards to the ball. There is also a 75-yard, 4-end put-up.

No uniform practice formerly prevailed in the trade with regard to the labeling of darning and mending cottons. The construction of the yarns was designated by some manufacturers as the number of ends and the number of plies per end; by others as the total number of strands, for instance, 4 ends of 2-ply yarn being indicated as an 8-ply yarn. The linear length per ball or spool was specified by some producers as the yardage of an individual strand and by others as the aggregate yardage of all the strands. This lack of uniformity in labeling worked disadvantageously to that element of the trade which reckons quantity not on the total yardage of the individual single yarns, but on the running yardage of the grouped yarn as it unravels from the ball. It also proved misleading and confusing to the consumer. To correct the inequalities resulting from this difference in trade practice, a majority of the manufacturers, estimated to produce 90 per cent of the mending cotton in the United States, adopted in a conference held in September, 1925, under the auspices of the Federal Trade Commission, the following unanimous resolution:

Resolved, That in the marking, labeling, or branding of mending cotton, the following and no other, with reference to the yardage, ends, strands, or ply, shall be marked on the package or ball and in the order stated: The yardage as it comes off the ball, or package; the number of ends; the number of plies per end.

This action taken by the industry was approved by the Federal Trade Commission and the requirements prescribed by the terms of the resolution were made effective as of February 1, 1926.

Knitting cottons.—Knitting cotton, so-called, is an unmercerized multiple-ply yarn of soft construction put up in ball form. Unlike darning cotton, knitting cotton is composed of but one end which consists of 3 or 4 single yarns doubled together with a slight twist. As knitting cottons are usually twisted dry they retain a fuzzy appearance and a woolly feel. Knitting cotton comes in sizes 2, 6, and 8 and rising progressively by even numbers on up to 24. They are used for knitting wash cloths, old-fashioned bedspreads, bags, children's hose, etc.

Crochet cottons.—In general there are two classes of crochet cottons, (1) the cabled, six-cord yarns, known in the trade as cordonnet, cordichet, crochet twists, etc., and (2) the 2-ply yarns, single twist.

The cordonnet cottons are firm, even, hard-twisted yarns, spun of high-grade, long-staple cotton, and are made principally in the mercerized finish. They consist of 3 ends of 2-ply yarn, twisted in two operations in the form of a cable. The ball form is a standard put-up for crochet threads. The numbering is arbitrary following the usage established abroad by the pioneer needle-work yarn manufacturers, the Dollfus-Mieg Co. of Mulhouse, Alsace. The common sizes are 3, 5, 10, 15, and 20, increasing by increments of 10 to 100 (size 90 omitted). Foreign yarns of this type are made also in coarser sizes and in the three fine sizes, 120, 150, and 200. Cordonnet cottons are primarily used for the crocheting of laces and insertions, lingerie edgings, Irish crochet, etc. Size 70 is put up in a small ball for tatting.

The most important of the 2-ply crochet yarns is the "pearl cotton," the anglicized name for the French "perlé" which is also frequently employed as a design ation for this type of cotton. Pearl

cotton is used not only for crocheting but also for counted-stitch embroidery, and for knitting by hand or machine. It consists of two single ends twisted together with a somewhat loose twist in a rope or cordlike effect. It is put up in both skeins and balls in sizes 3, 5, 8, and 12 following the cotton system of yarn numbering. Another 2-ply floss crochet resembling closely the finer sizes of perlé is put up in ball form in one standard size corresponding to a No. 10 2-ply yarn.

Embroidery cottons.—There are a number of so-called embroidery cottons differing from each other in the degree of twist and in the number of ends or plies of which they are composed. They may be conveniently divided into two groups as follows:

(1) The single-twist yarn, composed of two or more singles twisted together into a 2-ply or a multiple-ply yarn.

(2) Stranded, dividable cottons.

The 2-ply yarns for embroidery include the pearl cotton and crochet floss mentioned above under the category of crochet cotton. Pearl cotton is a large item of consumption for heavy types of embroidery such as hardanger work, net darning, Swedish weaving, French knots, cross-stitch, canvas work, and general embroidery on napery, household linen, and clothing. It is also used for making passementeries such as fringes, cords, and edgings and is employed as a substitute for silk cord by printers for programs, fancy cards, brochures, etc. Other 2-ply embroidery cottons are produced with a slacker twist than pearl cotton and are made in three sizes, rope, medium, and fine, for eyelet work and solid embroidery.

Couching yarn, used for a "tacking-down" stitch, large French knots, and braiding designs, is an example of a heavy 3-ply embroidery cotton.

There are several varieties of 4-ply embroidery cottons, such as the fast Turkey-red marking and monogram cottons made in sizes running in even numbers from 6 to 24. Another example of a 4-fold embroidery yarn is a so-called Broder or convent cotton which comes in sizes 16, 18, 20, 25, 30, 35, 40, 45, 50, and 60, and is designed for fine embroidering of monograms, eyelet work, and decorative stitching on infants' clothing, handkerchiefs, lingerie, household linens, and other articles of fine construction such as Madeira work, Porto Rican, and Philippine embroidery.

The stranded cottons used for almost all kinds of embroidery, cross-stitch, smocking, and tapestry work, and as a padding thread and foundation for monogram embroidery, are made up of three or more strands of 2-ply yarn, laid parallel, and given a twist barely sufficient to hold the strands together. The 3, 4, and 6 strand embroidery flosses are made in one size in skein form. The 6-strand embroidery cotton is also known in the trade as mouliné, conforming with the French usage. It may be used as a whole or divided into one or more strands, according to the effect and weight of the embroidery desired. These stranded flosses, which, in construction and twist, resemble the better grade mercerized mending cottons, are used interchangeably with them in the staple colors.

DOMESTIC PRODUCTION

Raw materials.—The raw cotton which enters into the production of thread yarns is a most important factor in the making of a high-grade cotton thread. The length, regularity, and uniformity of the staple of the cotton determine to a large extent the tensile strength of the thread. With the exception of five large companies equipped with spinning mills for handling the manufacture of the raw cotton into thread yarns, the majority of the thread concerns purchase their yarns in the open market or from yarn mills which spin on contract in strict accordance with specifications. The thread yarns imported are only a minor item, comprising for the most part fine counts for the production of household threads or gassed or processed yarns for occasional specialties.

Cotton thread of the better quality was formerly manufactured almost exclusively from yarns made of sea-island cotton, but since the decline of the crop yield, consequent upon the ravages of the boll weevil, Egyptian cottons have been substituted for sea-island in the manufacture of the higher grades of thread. At the present time about 80 per cent of the first-grade threads are made from imported Egyptian cotton.

The best Egyptian cotton consumed in thread manufacture is the Sakellarides or "Sak" cotton, the longest of which is about $1\frac{9}{16}$ inches in length. It is made into thread yarns ranging from Nos. 8 to 140, the low counts for the manufacture of shoe threads and threads for the bookbinding trade, where strength is a primary requirement, and the high counts for fine threads for such purposes as handkerchief hemstitching. Size 140 is the maximum in regular thread production, sizes exceeding this being specialties. The medium length Sakellarides Egyptian cotton averaging about $1\frac{1}{2}$ inches in staple is, as a rule, used for threads ranging from sizes 20 to 80; the shortest Sakellarides with a staple from $1\frac{5}{16}$ to $1\frac{7}{16}$ inches in length is used in thread yarns ranging from 20s to 60s. As the various grades of Sakellarides cotton have exceptional mercerizing properties, they are also the principal material used in the manufacture of the fine and better grades of crochet and embroidery cottons. While Sakellarides cotton is generally combed in the process of spinning, there is an appreciable amount of carded "Sak" cotton consumed in the manufacture of thread for use in the sole-sewing operations in shoe factories.

Cotton-thread manufacturers employ also a large quantity of Egyptian uppers, which are lower in price than the Sakellarides, averaging only about $1\frac{3}{16}$ inches in length of staple. This type of cotton, both combed and carded, is used for general utility threads, both for manufacturing and household use.

Of the domestic-grown cottons, the acclimated Egyptian or Arizona Pima cotton and three staple lengths of Peeler cotton are used in the manufacture of yarns for the thread industry. Pima cotton is utilized as a substitute for Sakellarides, but owing to limited crop production, manufacturers of thread have found irregularity in quality and length of Pima staple, which increases spinning difficulties. The Pima variety, like Egyptian uppers, is adapted to the production of general all-purpose threads, both for industrial and domestic consumption.

The first staple length of Peeler cotton, averaging $1\frac{5}{16}$ inches, is used for thread yarns from 10s to 70s in size; the second, with a fiber averaging $1\frac{1}{4}$ inches, enters into the production of yarns running up to the 40s, while the third, averaging $1\frac{3}{16}$ inches in length of staple, goes into the coarse yarns not exceeding 30s. The second and third staple lengths of Peeler cotton are sometimes substituted for Egyptian uppers.

Methods of production.—Conversion of yarn into thread includes the following operations: (1) Cop winding and doubling; (2) twisting and cabling; (3) reeling; (4) mercerizing, bleaching, or dyeing; (5) spooling or hank winding; (6) finishing and polishing; (7) spool, tube, or cone winding; (8) inspecting, labeling, and packing.

Sewing-thread production begins with the cotton yarn in the form of singles as it comes from the spinning frames. In the first stage, cop-winding, the single yarn is wound, without twisting, on to spools or wooden cores called doubler bobbins. For a 2-cord thread, two ends of singles are drawn from the mule cops or ring bobbins and wound parallel; for a 3-cord and a 4-cord thread, three and four ends, respectively, are grouped together on the bobbin. For heavy threads composed of coarse yarns and plies or cords ranging from 4 to 12, the single yarn is wound one end to a bobbin. In the next stage the requisite number of ends from the doubler bobbins are combined and twisted into a ply yarn on a twisting machine. The first twisting may be done either with or without water troughs, according to the type of yarn used and the thread desired. In the wet twisting system, which is preferable for unmercerized thread, the thread passes over and under brass rollers immersed in water-filled copper troughs for the purpose of laying the fuzzy projecting fibers and "setting the twist." For cable threads the necessary number of plied ends are given a final doubling on a so-called finisher twister. The product is then ready for the sequence of finishing operations such as bleaching, dyeing, and the special processes of dressing which prepare it for frictional resistance. Preliminary to these subsequent processes, it is reeled into skeins or hanks from the twister bobbins. After the completion of these operations the thread in hanks is spooled back again on supply bobbins preparatory to winding in final shape on cones, tubes, or spools for manufacturers' use and on small spools for household consumption. The goods are then ticketed, inspected, and packed in different size lots for shipment.

In the production of mercerized thread and handwork cottons the processes are generally as follows: (1) Beam warping, (2) gassing and mercerizing, (3) ball warping, (4) bleaching and dyeing, (5) beam winding, (6) quilling, (7) spooling, balling, or reeling.

Warping, the first stage, is a process in which the yarn from the twisting-frame bobbins is wound on to warpers' beams; the yarn is then passed over Bunsen burners for the purpose of singeing off the fuzzy projecting fibers. Following this it is mercerized, wound into ball warps, and subjected to the bleaching, dyeing, and drying processes. The yarn is then rewound on to beams preliminary to quilling. From the quills it is wound on spools or cones and is then a finished product, ready to be put up for the consumer. The thread or yarn on the cones supplies the spindles of the balling machines which wind the material on to small papier-mâché recep-

tacles or balls in convenient form for the seamstress. The yarn on the spools is reeled into small skeins for embroidery and crochet cottons. From this point on follow the processes of inspection, labeling, and packing.

Number of concerns.—Of the total United States production of manufacturers' thread, household spool thread, and handwork cottons, it is estimated that between one-half and two-thirds is the output of three large companies with international affiliations. The remainder is made by 35 or 40 moderate-sized manufacturers and by a hundred or more small converters. In addition, a large number of jobbers and wholesale supply houses buy unlabeled thread which they spool and distribute under their own brands and trade names, thereby entering into direct price competition with the bona fide thread producers.

Geographical distribution.—The thread industry is localized for the most part in New England, Massachusetts having the largest number of mills. Rhode Island, Connecticut, New Jersey, and Pennsylvania are the next States in order of importance. There are also a few scattered mills in Wisconsin, Illinois, Michigan, Ohio, and Indiana. New York City is the focal point for the large number of small manufacturing jobbers and converters who cater to the metropolitan trade.

Organization.—The thread industry is so organized that no clear-cut division in the processes of manufacture differentiates the converter from the legitimate manufacturer. Thread production is highly diffused, units in the industry ranging in size and complexity of organization from small "job shops" conducting a commission or partial assembling business to the three large companies, with a capitalization of many millions of dollars, each consisting of several separate mill units, with more or less specialization of product. In the middle ground, between the numerous small shop concerns and the three large companies, are the rank and file of the old-established thread manufacturers, the majority of whom carry on all thread-making operations except the spinning of the yarn from the raw cotton in the bale.

Specialization.—Two of the three large thread companies confine themselves chiefly to the manufacture of domestic or household spool thread, and embroidery, crochet, and other cottons for handwork. Their output in these lines comprises a high percentage of the entire United States production. The bulk of the production of the third company is manufacturers' thread, but a proportion of its output consists also of a full line of household and domestic goods. It has been estimated that 90 per cent of the household thread and handwork cottons of the United States are produced by the three large concerns, leaving 10 per cent of the business in the hands of the independents and a number of firms specializing in art needlework and stamped goods.[2]

Manufacturers' thread is the principal output of the independent concerns. Before the war it was estimated that about 30 to 40 per cent of the entire production of manufacturers' thread in the

[2] These companies handle the materials for fancy cushions, scarfs, bedspreads, bags, dresses, lingerie sets, curtains, neckwear, table linen, and other articles cut to pattern and stamped with designs ready to be embroidered. Stamped goods are usually put up for sale in "package outfits," each containing the sewn and stamped article with directions for working and with a sufficient quantity of the appropriate kind and color of embroidery cotton inclosed to execute the design.

United States was made by them;[3] the share now held by these companies is estimated to have increased to about 50 or 55 per cent of the total for the country. About one-half or less of the manufacturers' thread business is produced by the three large companies at the present time.

The other portion of the manufacturers' thread output in the United States is about equally divided between the 35 or 40 so-called independents and the many small converters situated in the metropolitan area. The latter generally specialize in one or more lines, and in most cases confine their production to a single type of soft-finished thread of cheap construction, primarily for the garment and cutting-up trade in New York or in outlying districts. Only one of the metropolitan converters markets a thread for household use.

Southern yarn mills have in recent years offered for certain industrial sewing and stitching purposes an appreciable volume of plain grey twisted thread yarn on cones that is not finished by special dressing processes, but which represents the regular run of the mill. This development, the result of improvements in sewing machines permitting the use of a more varied line of thread, is operating to make the spinning mills competitors of the thread manufacturers in certain channels of consumption, a class of competition unknown a decade ago.

Diversification of production.—The products of the thread industry have become in the past few decades more and more diversified. The constant improvement made in industrial sewing machines has gradually expanded the thread requirements of the various consuming industries. The thread manufacturer has as a result been obliged to study improvements in technique and to initiate innovations to meet these new developments. Moreover, it has become necessary for the thread manufacturer to cater more and more to the demands of consumers—demands which are often a matter of whim or preference, custom, or tradition. To meet competition, he must sell anything in the line of thread to any manufacturing customer in the form desired. The thread business has been likened to a public-service institution—a business of accommodation—since the degree of success of the thread manufacturer depends upon the service which the product gives and his facility to conform to customers' desires. Catering to public demand, which has become one of the essential requisites in this industry, has resulted in an enormous pyramiding of varieties of products. One of the large producers of thread manufactures over 50,000 kinds, quality brands, twists, finishes, sizes, colors, and put-ups, 26,000 different items being constantly kept in stock. A production numbering 10,000 articles of different qualities and descriptions is a moderate-sized assortment. Standardization of the industry with a reduction in the excessive diversity and an increase in interchangeability of thread has been attempted and is constantly being encouraged by thread manufacturers. Difficulties are encountered, however, in this work, owing to the multiplicity of needs of the consumers, their conservatism and arbitrary demands, and to competition between the manufacturers themselves.

[3] Petition in equity, *United States of America* v. *American Thread Company et al.*, unpublished decisions. June, 1914.

Comparison of yarn and thread industries.—Up to a certain point the cost of production of thread is determined by the same factors that apply to yarns—i. e., by the type and staple length of the cotton used, the method of spinning, the size, twist, finish, manner of winding, and length of the finished put-up. The two industries differ, however, in certain respects and their costs are more or less affected thereby. In the first place, the yarn manufacturers' machinery is equipped for large contracts, while the thread manufacturers' machines must be adaptable to changes for comparatively small lots of particular types of thread. In the second place, thread production requires attention to many fine details, and adjustments which must be made with precision to insure a high-quality output. The very success of the thread industry depends on the quality of the product, its service, and wear. Threads are subjected individually to constant strain under the high speed and tension of the modern power-sewing machines in factory production. Imperfections of any kind arising from uneven twisting or spinning or the lack of proper finish cause breakage in the machine and halt operations. Yarns, on the other hand, are not subjected individually to any such mechanical strain. Because of the necessity for quality standards, the thread industry requires more hand labor and more inspection than does either the yarn or cloth industry. Furthermore, the thread manufacturers, who pride themselves on high repute for quality standards, usually maintain service departments employing technically skilled persons who advise with manufacturing consumers as to the behavior of the thread in machines. Complaints are investigated and adjustments are made if the thread does not conform to specifications or if it developes imperfections. The service rendered by thread manufacturers in guaranteeing their product is a factor of importance in their expenses of production.

Distribution is a third factor of difference between the yarn and the thread industries. The average yarn manufacturer chooses his customers discriminatingly and sells his output in large units. The thread manufacturers, on the other hand, must serve the public and accommodate countless small manufacturers and retailers who buy from hand to mouth and in lots as small as 5 pounds or even less. The small lot distribution is one of the banes of the thread industry. As a result of the reluctance of consumers to stock up beyond their immediate requirements, the depot system of distribution has grown up within the thread industry. These so-called depots that the larger manufacturers maintain in various sections of the country are essentially branch houses with separate sales forces. Each depot has to carry a full line of stock of the different types and kinds of threads for distribution to purchasers in its area, and the total reserve stock thus carried by the manufacturers entails the tying up of large amounts of capital.

History of the industry.—Although it is probable that the manufacture of cotton thread was begun on an experimental scale in this country, coincident with the establishment of the industry in Scotland at the beginning of the nineteenth century, the historical records preserved do not mention industrial production in the United States until several years after importations of thread from Scotland commenced in 1820. The first foreign shipments of spool sewing cotton into this country were of three-cord thread. Technical developments

in the industry abroad in the two following decades brought about the manufacture and exportation of a 6-cord thread, which was superior in tensile strength, stability of twist, and attractiveness of put-up, to the earlier 3-cord variety. During this period several domestic mills initiated the manufacture of thread in a somewhat desultory manner, but production difficulties attendant upon the combing and spinning of fine count yarns of long staple cotton for 6-cord thread resulted in failures. For a long time, therefore, the domestic output was restricted to the coarser numbers of the more inferior 3-cord thread.

About the middle fifties mechanical and chemical processes were invented for finishing thread with a silk luster, a treatment of polishing which enhances the tensile strength and frictional resistance of the thread. This innovation, called a silk-finished or glacé thread, was introduced into the United States from Scotland. Because of the strength-increasing properties given thread by this new patented process, the hopes and ambitions of the few domestic producers who had persevered in the face of trying obstacles and discouragements were revived and thread production was given a new impetus.

At this time the Willimantic Linen Co., of Willimantic, a borough of Windham, Conn., which had for many years been manufacturing linen fabrics and threads, was compelled to turn its attention to cotton thread production owing to the shortage of flax after the outbreak of the Crimean War. This company purchased the manufacturing rights for the production of the glacé thread. It succeeded in building up a substantial business and took over the Willington Thread Co., of Willington, Conn., established in 1844, the first company to obtain a license for glacé thread in this country. The success of this new invention for finishing thread also stimulated a number of other manufacturers to devise new methods of processing threads with a satin luster. As a result several competing companies were founded in Pawtucket, R. I., and Fall River, Mass. By the beginning of the Civil War, the domestic industry had attained a promising position, and under the stimulus of war conditions the demand greatly increased.

Another opportune circumstance—the invention of the sewing machine—offered an additional incentive for the improvement and expansion of production of the comparatively new 6-cord thread which, up to this time, had been made in this country with meager success. As the 3-cord thread then produced did not possess the requisite tensile strength to withstand the friction of the sewing machine, the demand for the superior 6-cord thread for sewing-machine use grew to such proportions that the manufacturers in this country were obliged either to comply with the new market demand or retire from business.

The increase in tariff duties on cotton thread during the Civil War was the third influence to stimulate the growth of the infant industry. It had the additional result of attracting foreign capital to the United States. Branch mills were established in this country by several of the large European thread producers. The Clark Thread Co. of Scotland, founded a plant with the same name at Newark, N. J., which commenced operation in 1865. A few years later the firm of James Coats, of Paisley, Scotland, acquired the stock of the Conant Thread Co., at Pawtucket R. I.; in 1912 the firm name was changed

to J. & P. Coats (Inc.). In 1883, John Clark, Jr., & Co., not connected with the other institutions established previously, set up a mill in New Jersey under the name of Clark Mile-End Spool Cotton Co. About this time, James Chadwick & Bro. (Ltd.), another English company, began to operate a company at Jersey City.

Under the management of Hezikiah Conant,[4] who had supervised the Conant plant purchased by Coats at Pawtucket, the Willimantic Linen Co., which still retained that name in spite of being diverted entirely to the production of cotton thread, continued to expand. In its consolidation with the Willington Thread Co., as already mentioned, it had acquired the services of Timothy Merrick, who later became the founder of the Merrick Thread Mill, at Holyoke, Mass. The Willimantic Co. thus became at an early date a dominating factor in the industry, in a sense the parent company of the pioneer thread manufacturing concerns of the United States. Other companies were established about the period of the Civil War, the largest ones being the Hadley Thread Mills at Hadley, Mass., the Williston firm of East Hampton, Mass., and the Gardner Hall, jr., firm of South Willington, Conn. By 1890 there were 34 companies with a personnel of 9,220 and a capital of nearly $28,000,000.[5]

In the late nineties and the first decade of the present century the thread industry entered upon an era of consolidation both here and abroad. The Coats business at Paisley, Scotland, which had been incorporated in 1890 as J. & P. Coats (Ltd.), with a capital at that time of over $27,000,000, absorbed in 1895 the firm of Kerr & Co., of Paisley, and in the following year purchased its chief rivals, the Clark Thread Co., of Paisley, and the concerns of James Chadwick & Bro. (Ltd.), of Bolton, and Jonas Brook & Bros. (Ltd.), of Meltham. The Clark Thread Co. (Ltd.) had previous to this merger with the Coats interests acquired control in the United States of the Clark Mile-End Spool Cotton Co. of New Jersey. It took over also the Chadwick mill in Jersey City. Thus the three New Jersey plants, consolidated under the Clark Co. of Newark, became by the merger of the parent company of Scotland a part of the J. & P. Coats enterprise.

In addition to the amalgamation of the Coats and Clark interests, there occurred in 1897 the merger of a dozen or more thread companies in England into a corporation known as the English Sewing Cotton Co. (Ltd.), with a capital of $11,250,000. At the outset this new company became allied with J. & P. Coats (Ltd.), which took shares of the common stock, valued at approximately a million dollars, half of which was later sold. J. & P. Coats also extended financial assistance to the English Sewing Cotton Co. during a subsequent period of reorganization[6] of the affairs of the concern.

In the United States the first big merger of domestic companies was the American Thread Co. This concern was organized in 1898 to acquire title to the common stock, plants, and stocks in trade of 14 domestic companies. The disastrous price cutting at that time prevailing in the thread industry and the custom of large manufacturers of extending long-period credits to the trade—terms which the smaller firms were financially unable to duplicate—had brought these firms to the verge of bankruptcy. The severity of the competition

[4] Davis, W. T., *The New England States*, pp. 163–165.

[6] Macrosty, H. W., *The Trust Movement in British Industry*.

practically forced them into the position of being unable to refuse options to purchase their plants. The constituent companies in the consolidation were as follows:[7]

	Established
E. J. W. Morse Co.,[8] Boston, Mass	1834
Willimantic Linen Co.,[9] Willimantic, Conn	1854
Hadley Co., Holyoke, Mass	1863
The Warren Thread Co., Ashland, Mass	1865
Merrick Thread Co.,[10] Holyoke, Mass	1865
J. O. King & Co., New York, N. Y	1866
Barstow Thread Co.,[11] Providence, R. I	1866
The National Thread Co., Mansfield, Conn	1873
Glasgo Yarn Mills Co., Glasgo, Conn	1881
Kerr Thread Co., Fall River, Mass	1881
Morse & Kaley Manufacturing Co., Milford, N. H	1882
Glasgo Thread Co., Worcester, Mass	1883
The William Clark Co., Westerly, R. I	1891
The Ruddy Thread Co., Worcester, Mass	1891

By January, 1903, the above-mentioned companies were all dissolved and their property merged into the American Thread Co. The machinery and inventories of several of the smaller firms in the more remote localities had been transferred to the largest and most centrally located plants.

The following reasons were advanced for the consolidation [12] in the prospectus issued in 1898:

> The business of the above companies has for a considerable time been injuriously affected by excessive competition among themselves, and the cutting of rates having, during the past three years resulted in a very large portion of the trade being done below cost of production, it was realized that a complete consolidation of the various interests was necessary to insure renewed prosperity. * * *

The benefits to be derived by the union were set forth as follows:

> Where practicable, it is intended that at least one partner or one director in each of the undertakings acquired by the company shall continue in responsible management. The individual experience of those actively engaged in directing the various businesses will thus be combined for the benefit of all; but the management of all the businesses will be under one central control, and the disadvantage of carrying on the various processes of spinning, doubling, finishing, and spooling in each of the mills will be avoided by concentrating in each manufactory the particular work it is best suited to do. This will considerably cheapen production, whilst, on the other hand, very large savings will be effected in the expenses of distribution, which have been enormously heavy in the past, not only on account of each one of the 13 companies having a separate selling organization, but also through the keenness of their competition one with another, resulting in excessive expenditure in various ways, the free distribution of cabinets and other advertising matter alone amounting to a very large sum.[13]

The capital stock of the Willimantic Linen Co., the largest of the merging companies, had previous to the consolidation been acquired by the English Sewing Cotton Co. (Ltd.). In the financial transactions incident to the merger, the latter took over practically all the common stock of the American Thread Co., thereby securing almost the sole voting power in its affairs. J. & P. Coats (Ltd.) at the time

[8] Including patent rights, machinery, and good will of the Morse Machine Co.
[9] Including spool factory in Maine and rights of birch and poplar stumpage.
[10] Including factory in Maine for manufacturing wood spools and packing cases.
[11] Including good will and trade-marks of Alexander King & Co.
[12] Report of the Industrial Commission on Trusts and Industrial Combinations, 1901, Vol. XIII, p. 36.
[13] Another important benefit was the elimination of trade abuses. All sizes of manufacturers' thread had been sold at one price, notwithstanding the wide difference in cost between the fine and heavy yarn counts. This unsound practice was abandoned in favor of a scientific selling list yielding approximately the same margin of profit on all items belonging to the same line or brand mark.

of the organization of the American Thread Co. applied for approximately $500,000 worth of preferred stock.[14] The acquisition of this block of preferred stock by Coats and the transfer of common stock to the English Sewing Cotton Co. (Ltd.) which, as already stated, had previously become financially allied with the Coats enterprise abroad, made the three most important thread companies in the United States, viz, the Clark Thread Co., of Newark; J. & P. Coats (Inc.), of Pawtucket; and the American Thread Co., of New York, connected in one way or another with the J. & P. Coats concern of Paisley, Scotland.

As a result of a suit in equity instituted by the United States Government, the financial relationship of the Coats business here and abroad with the American Thread Co. and the English Sewing Cotton Co. (Ltd.) was terminated in 1914. By a decision rendered in that year by the District Court of the United States for the District of New Jersey,[15] J. & P. Coats (Ltd.), James Chadwick & Bro. (Ltd.), and Jonas Brook & Bros. (Ltd.), of Great Britain; J. & P. Coats (Inc.), of Pawtucket, R. I.; the Clark Thread Co, the Clark Mile-End Spool Cotton Co., and George A. Clark & Bro., of Newark, N. J., together with the selling agency, the Spool Cotton Co., were jointly and severally enjoined from "acquiring, or, after January 1, 1915, from holding, directly or indirectly, any pecuniary or property interest whatsoever in the capital stock or other securities" of the American Thread Co., the English Sewing Cotton Co., or their sales organization, the Thread Agency.

Domestic production and consumption.—Statistics issued by the Bureau of the Census do not indicate the output of crochet, darning, embroidery, and knitting cottons put up for handwork, figures for these being merged with the statistics of yarn production. Census reports, moreover, fail to segregate the sewing-thread production for retail trade and production for industrial consumption. However, it is estimated by competent authorities in the industry that the quantity of sewing thread produced for the manufacturing industry is between two and two and one-half times the quantity produced for household use.

On the other hand, the value of the output of manufacturing thread does not bear the same ratio to the value of thread for household sewing because of the greater cost of the short-length put-ups in the production of articles for home consumption. Yet, in spite of this fact, the value of thread for manufacturers' use is approximately double that of thread and cottons for retail sale.

Production of manufacturing thread has assumed the lead quantitatively largely as a result of the technical improvement in industrial sewing machines which had made possible mass production of articles formerly made exclusively in the home. Needlework, which was a general and necessary occupation in the home a generation ago, has, with the changed economic status of women, fallen into comparative neglect. Dexterity in sewing has declined with the availability of large assortments of factory-made wearing apparel for men, women, children, and infants, as well as with the availability of house furnishings of all kinds in price ranges suitable for all purchasing con-

UNIVERSITY OF MICHIGAN LIBRARIES

stituents. Moreover, much of the time of women nongainfully employed, released in recent years by the invention of labor-saving devices, has been diverted to other channels of activity. Modern conditions and standards of living and the pleasures now offered by the automobile, radio, and moving pictures have also lessened the time given to needle craft. Transitions in fashions have been another strong factor in the decline of cotton-thread consumption in the home. The simplicity of the mode and the narrow straight-line silhouette in vogue during the past few years have brought about a lessening consumption of household thread. Furthermore, the popularity of silk apparel has shifted some of the domestic demand from cotton to silk spool thread. With the declining demand for household spool sewing thread of cotton, the two large companies which practically control the bulk of this business in the United States are placing increased emphasis on production of an extensive range of handwork cottons, many of which were formerly imported.

The basic unit of sales and production in most thread mills is the number of dozens of 200-yard spools, or 2,400-yard units, the various types and put-ups of thread being all converted to this unit of length as a basis of computation. It is the consensus of opinion among large thread producers that a No. 36 three-cord thread, which averages theoretically 10,080 yards to the pound, represents a fairly accurate annual average size of all the different kinds of household and manufacturers' sewing thread produced in the United States for a period of years. Using this as a conversion factor, the production as reported by the Bureau of the Census in pounds has been converted to a yardage basis in order to facilitate comparison in a later section with the import statistics which are stated in units of 100 yards.

Table 3 gives the official figures for the value and pounds of the cotton sewing thread production of the United States for two decennial, four quinquennial, and three biennial censuses. The last two columns of the table have been computed to show the approximate equivalents, of the recorded pounds, in 100-yard units and in dozens of 200-yard spools.

TABLE 3.—*Cotton thread—Domestic production, 1890–1925*

[Source: Bureau of the Census]

Year	Value [1]	Pounds [1]	Approximate equivalent in 100 yards [2]	Approximate equivalent in dozens of 200-yard spools [2]
1890	$11,637,500	13,868,309	1,397,925,547	58,246,898
1899	11,908,671	15,907,058	1,603,431,446	66,809,644
1904	15,043,043	17,163,741	1,730,105,093	72,087,712
1909	20,516,269	23,700,957	2,389,056,466	99,544,019
1914	22,917,099	26,507,023	2,671,907,918	111,329,497
1919	55,009,176	26,441,943	2,665,347,854	111,056,161
1921	50,201,996	23,275,618	2,346,182,294	97,757,596
1923	55,311,320	31,645,537	3,189,870,130	132,911,255
1925	59,875,776	37,585,368	3,788,605,094	157,858,546

[1] Bureau of the Census.
[2] Conversion factor: 10,080 yards=1 pound.
[3] In 1870 production of 11,560,241 dozens of spool cotton was reported by the Census—the only year in which this unit of quantity was employed.

As indicated by these figures, thread production which amounted to almost 16,000,000 pounds in 1899 increased 50 per cent in the following decade and continued to expand, reaching approximately 26,500,000 pounds at the beginning of the war. While steadily on the upgrade during this 15-year period, it had not kept pace, however, with expansion in most other branches of the cotton industry, a fact which may be attributed in part to the effect of the consolidation of the producing companies on the more accurate approximation of supply and demand.

During the war nearly every thread concern increased its facilities for production and many new concerns were inaugurated, particularly in the manufacturers' thread business. The productive capacity, therefore, of the thread industry was considerably larger in 1919 than in 1914. Census figures, however, do not reflect an increase in production at the end as compared with the beginning of the war period. This was probably due to market conditions then obtaining, since a reduced output in 1919 as compared with pre-war conditions was also noted abroad. In the fiscal year 1918–19, the production of J. & P. Coats (Ltd.), of Paisley, was 20 per cent less by weight than in the year 1913–14.[16]

The depression in trade which affected the thread industry severely in 1920 reduced production in 1921 over 3,000,000 pounds as compared with the output reported at the previous census and brought it even below the figure for the year 1909. In 1923 the industry had recovered and production had advanced to 31,646,000 pounds. This was an exceptionally big year in the thread industry and according to manufacturers represented a market demand 10 per cent above average. Even this large putput was exceeded by the record production of 37,585,000 pounds in 1925. The production of cotton thread is considered by competent men in the industry to be at the present time far in advance of consumption. It has been estimated by one well-informed manufacturer that the total United States consumption, plus exports, of thread is at the present time only about 50 per cent of the amount which could be manufactured if all the thread companies operated to 90 per cent of their capacity without overtime work.

Production figures, other than those of the Bureau of the Census, are not available, as thread manufacturers, both at home and abroad, are extremely reluctant to divulge statistical information concerning the industry. Production data in particular are jealously guarded, and manufacturers are unwilling to cooperate in furnishing such information even to their own trade bodies. Although there were until recently two trade associations [17] devoted to the interests of the industry in the United States, neither of them compiled any statistics of production.

Production of darning, mending, knitting, and crochet yarns, for which no census figures are available, was carried on in the United States on a small scale prior to the war. There was virtually no production of mercerized hand embroidery cottons, however, as the demand was mainly for Alsatian and English brands.

[16] Great Britain Board of Trade Standing Committee on Trusts, Findings on the Alleged Existence of a Combine Among Manufacturers of Sewing Cotton, Feb. 3, 1919, p. 4.
[17] One of the trade associations, composed of New England manufacturers, disbanded in 1926.

UNIVERSITY OF MICHIGAN LIBRARIES

During the war, when imports of cotton handwork yarns were greatly curtailed, a number of American manufacturers seized the opportunity created by the war exigencies to produce a domestic substitute similar in put-up, method of numbering, and general appearance. On the renewal of European competition after the war, some of these firms found themselves unable to compete and discontinued this line of work; a few, however, have been more successful and have not only continued to maintain the footing they had acquired in the domestic market, but have carried on a small export business.

DOMESTIC EXPORTS

Extent.—Exports of cotton sewing thread and cottons for handwork were not recorded in Commerce and Navigation of the United States prior to 1918. The statistics available for 1918 to 1922 are an aggregate of both cotton sewing thread and crochet, darning, and embroidery cotton for handwork. In 1922, however, segregation was begun, making available figures for the quantity and value of the exports of both groups. These are shown in Table 4.

TABLE 4.—*Domestic exports of cotton sewing thread and crochet, darning, and embroidery cottons, 1918–1926*

Calendar year	Total sewing thread, and crochet, darning, and embroidery cottons		Cotton sewing thread		Crochet, darning, and embroidery cottons	
	Pounds	Value	Pounds	Value	Pounds	Value
1918	(1)	$2,824,776	(1)	(2)	(1)	(2)
1919	(1)	4,367,762	(1)	(2)	(1)	(2)
1920	(1)	4,471,617	(1)	(2)	(1)	(2)
1921	(1)	2,055,328	(1)	(2)	(1)	(2)
1922	1,944,640	2,034,732	1,653,184	$1,781,221	291,456	$253,511
1923	1,809,013	2,065,520	1,583,423	1,819,478	225,590	246,042
1924	1,534,873	1,772,668	1,405,768	1,599,698	129,105	172,970
1925	1,058,155	1,183,347	960,454	1,047,298	97,701	136,049
1926	1,422,669	1,439,862	1,299,269	1,280,158	123,400	159,704

[1] Not reported.
[2] Not separately reported.

In 1918 aggregate exports of sewing thread and of cottons for handwork amounted to approximately $2,825,000. In the two following years, 1919, 1920, there was a sharp advance in the value of exports. This increase, being coincident with the peak of inflation, is probably more a reflection of the higher price level obtaining at the time than an indication of any appreciable expansion in trade.

After 1920 there was a steady decrease to 1925, when the combined exports of sewing thread and cottons for handwork amounted to only $1,183,347, the lowest value in the eight-year postwar period for which statistics are at hand. In 1926 exports totaled $1,439,862 in value, showing an increase over the low record of 1925. The slump in exports above noted is indicated also in the quantity figures available since 1921. Exports, which amounted to about 1,945,000 pounds in 1922, declined to 1,058,000 pounds in 1925 and recovered to approximately 1,423,000 pounds in 1926.

It is interesting to note from Table 4 that while exports of sewing thread have fallen off in both quantity and value, their ratio to the combined exports of both sewing thread and handwork cottons has increased. While the exports of crochet, darning, and embroidery cottons represented in 1922 nearly 15 per cent of the total volume of exports of the two groups together, in the past three years they have averaged only 8.7 per cent of the total. Sewing thread, on the other hand, increased from 85 per cent of the total in 1922 to 91.6 per cent of the total in 1924, and this latter ratio, approximately, has been maintained in the two subsequent years.

Markets.—The largest volume of sewing-thread shipments from the United States goes to the Philippines, which take on an average between 40 and 50 per cent of the total exportable surplus. Exports to Canada, the largest foreign customer, generally amount to over one-fourth of the total. After these two, the most important purchasers in 1926 were Australia, which took about 8 per cent of the total, followed by Mexico with approximately 6 per cent, and China, Brazil, and Cuba with between 1 and 2 per cent each. The remainder is widely distributed among a large number of countries, none of which is an important purchaser individually. The exports of sewing thread consist largely of manufacturing thread, shoe thread being an important item, particularly in the shipments to Australia.

For the small amount of handwork cottons exported from the United States, the principal market is Canada, which imported 38 per cent of the total in 1922, nearly 45 per cent in 1923, 55 per cent in 1924, 33 per cent in 1925, and 37 per cent in 1926. In 1926 Argentina, Mexico, and the Philippines, in the order stated, were the next best markets. Tables 5 to 7, inclusive, indicate the principal markets for American-made sewing thread and handwork cottons.

[1] Includes the following quantities of crochet, darning, and embroidery cottons not separately shown in Table 6: 1922, 1,255 pounds; 1923, 1,166 pounds; 1924, 529 pounds; 1925, 1,044 pounds; 1926, 4,837 pounds

Factors limiting exports.—In regard to domestic or household thread, the affiliation of two of the largest producers in the United States with J. & P. Coats (Ltd.), of Paisley, Scotland, and the connection of the third large concern with the English Sewing Cotton Co. (Ltd.), of Manchester, England, tend to make the output of sewing thread of the three principal companies in the United States serve primarily the requirements of the American market. The two British firms mentioned are vitally interested in international trade, exporting over 80 per cent of the output [18] of their home factories. One of them also maintains branch plants in various foreign countries which cater to the demand within the respective national borders.

A second possible cause of small exports is the fact that owing to the higher American wage scale, production costs in this country may be greater than abroad. Because of the general market shortage, a considerable amount of American-made thread was exported

[18] Great Britain Board of Trade Standing Committee on Trusts, Findings in Alleged Existence of a Combine Among Sewing Thread Manufacturers.

during the war and until European production returned to normal. When the European manufacturers, particularly the two British thread companies, were again in a position to reassert their former competitive strength, American exporters were under the necessity of relinquishing their temporary gains which had originated out of war exigencies.

In regard to handwork cottons, the relatively small exports from the United States are due to the heavy competition which the few American producers of these goods encounter in foreign-trade markets from the goods of certain Continental manufacturers, particularly the Dollfus-Mieg Co. of Mulhouse. Its products, trade-marked "D. M. C.," predominate in international trade in this line and have practically a monopoly in many markets. In countries having but few urban centers and a large agricultural population with low purchasing ability, price, not brand, is the first consideration. In such countries, the Dollfus-Mieg cottons, which sell for higher prices than competing foreign brands, have not obtained a permanent hold.

Several reasons have been advanced for the competitive strength of this Alsatian company. Established in 1746, it is, in the first place, virtually the pioneer in the field of embroidery cottons. The D. M. C. cottons have been used in Europe for generations and even in this country have been a household word for over half a century. This company has, moreover, in its long history, acquired an intimate knowledge of the peculiar trade conditions in each country, and established sales organizations and distributing depots in central points throughout Europe. The availability of large stocks in warehouses in these central locations increases this company's competitive strength by permitting the safe, quick, and inexpensive delivery of small-lot orders to wholesalers and retailers, who buy for immediate requirements, thus obviating delays in transmission through customs.

Another factor which has aided the Dollfus-Mieg Co. in establishing the popularity of its products is the quick response of the company to style changes. An American consul has stated:

> The variations in style cause a great deal of difficulty to a foreign manufacturer, and this difficulty increases in proportion to his distance from the market. Thus, the French firm can keep in touch with changes in style and demands for colors and supply its warehouses immediately with new colors or with increased quantities of colors whose demand warrants it. This firm carries over 380 colors of yarn, according to its sample card, and two or three times a month it offers a new shade to its agents and customers. This is the principal difficulty with which American exporters of yarn will have to contend.

A still further advantage held by foreign producers of handwork cottons in competing successfully in the European market is the matter of price. Probably because of lower labor costs of foreign manufacturers, crochet and embroidery cottons of grades which compare favorably with the American product are retailed abroad at practically the same price as American wholesale quotations. In some countries, silk embroidery flosses may be obtained for substantially the same money as similar American goods made of cotton. This, in conjunction with the fact that consumers of crochet and embroidery cottons are very conservative and skeptical as to the color fastness of new, untried yarns and reluctantly change from any accustomed brand, makes the stimulation of interest in American handwork cottons in Europe a difficult matter.

UNIVERSITY OF MICHIGAN LIBRARIES

FOREIGN PRODUCTION

Great Britain.—Scotland became at an early date the birthplace of the cotton-thread industry. In the first quarter of the eighteenth century there sprang up in Paisley and neighboring towns many small mills engaged in the twisting of linen thread by hand on twisting appliances imported from Holland. When the inventions of Arkwright and Crompton placed on the market the fine count cotton yarns from Lancashire, many of these mills began the production of cotton thread. The Clark firm had its beginnings in Paisley, manufacturing linen thread for heddles and loom harnesses. The curtailment of the imports of silk used for the loop or eye of the heddle, which occurred as a result of Napoleon's Berlin decree in 1806, was a circumstance which led the Clark firm to perfect a cotton-thread substitute for the former silk heddle yarn. The company branched out into the production of cotton sewing thread, which it placed on the market for the first time in 1812.

The Coats concern is the outgrowth of an interest which James Coats, a Canton-crêpe weaver of Paisley, held in a small thread mill supplying him with yarns of the special twist required in his business. James Coats expanded his interest in this line and established a thread mill at Ferguslie which became the nucleus of the present works located there. Both the Clark and Coats companies were aided in the establishment of their industries by the decline of the Paisley shawl industry which threw on the market a large amount of cheap labor. This was an important factor in the localization of the thread industry in and about Paisley.

In 1889 the firms of Clark and Coats formed a sales combination for the purpose of effecting economies in distribution. Headquarters for this selling organization, known as the Central Agency, were established at Glasgow. It also marketed the products of James Chadwick & Bro. (Ltd.), of Bolton, and later was intrusted with the distribution work of Jonas Brook & Bros. (Ltd.), of Meltham, and also that of the English Sewing Cotton Co. (Ltd.).[19] The primary function of this agency was the regulation of sales, collection of accounts, and maintenance of traveling salesmen with an apportionment of expense among constituent companies. This sales combination made the way clear for a consolidation in 1896 of the Clark and Coats companies, together with Jonas Brook & Bros. (Ltd.), and James Chadwick & Bro. (Ltd.). Each company continued to maintain its separate name, trade-marks, and organization, and profits were distributed among the shareholders of J. & P. Coats (Ltd.). In addition to the above-mentioned companies, J. & P. Coats (Ltd.), own the capital and control the operation of Kerr & Co. (Ltd.), and I. P. Clark & Co. (Ltd.).[20] The company also acquired a coal mine and a large block of the common stock of the Fine Cotton Spinners' and Doublers' Association, which facilitated their access to supplies of raw material.[21]

The balance sheet of J. & P. Coats (Ltd.), which is now largely a holding corporation, shows for the fiscal year 1926 a capital of

$98,546,625, reserves of $23,513,015, and total assets of $154,264,064. Of these, fixed assets total $80,258,883, consisting chiefly of shares in and permanent loans to subsidiaries. The company controls and largely finances by means of advances to them for stock and working expenses not only the companies mentioned above but also a number of subsidiary concerns and branch factories abroad. According to the 1926 balance sheet these companies owed J. & P. Coats (Ltd.), a sum of over $27,662,519, for advances and dividends receivable. In 1896, at the time of the amalgamation of the four concerns, the property of Coats comprised 16 factories, including mills in the United States, Canada, and Russia, and 60 branch houses. The company also maintained more than 150 depots in all parts of the world.[22] Information is not available concerning the subsidiaries, branch houses, and depots of the concern at the present time, but in the 30 subsequent years there has been without doubt a considerable expansion. The foreign branches of J. & P. Coats (Ltd.), at present established abroad, are located in the following countries: The United States, Germany, Belgium, Switzerland, Italy, Spain, Portugal, Russia, Poland, Austria, Hungary, Czechoslovakia, Mexico, Brazil, and Japan. The branch factory sells its product for the most part in the country in which it is located.

The English Sewing Cotton Co. (Ltd.), of Manchester, England, is the second British thread concern in importance. Primarily a holding corporation, it has a controlling interest in 17 enterprises,[23] the most important of which is, as already mentioned, the American Thread Co., of New York. In the original amalgamation were included 11 cotton sewing-thread manufacturers, a linen thread manufacturer, a silk throwster, and a silk thread producer. There were also obtained through this amalgamation a subsidiary in France and in Canada. The English Sewing Cotton Co. later acquired two other British concerns, including a subsidiary mill in Barcelona, Spain. The last-named was placed some years after under a management controlled by Coats; the French factory at Armentieres was subsequently destroyed during the war. In 1926 the capital of the English Sewing Cotton Co. amounted to $19,260,118 and its assets totaled $28,131,285.

In addition to these two outstanding producers, there are over 60 other manufacturers of sewing cotton in the United Kingdom. The production of the Coats company constitutes the greater part of the output of the entire country. In the investigation of the sewing-cotton subcommittee of the Standing Committee on Trusts in Great Britain in 1920 it was found that 80 per cent of the "domestic sewing cotton" sold by the Drapers' Chamber of Commerce in Great Britain was the Coats' product. Although the precise extent of the hold which Coats have of the British home trade can only be a matter of individual opinion, the findings of the committee show that the Coats concern for a number of years has been sufficiently strong to maintain an effective monopoly on sewing cotton for household use.

No figures for thread production in Great Britain are available.[24] In the absence of production figures the volume of export trade serves

[22] Macrosty, H. W., *The Trust Movement in British Industry*.
[23] *Statist*, July 21, 1923.
[24] Even during the investigation by the sewing-thread subcommittee of the Standing Committee on Trusts, the accountants of the British Government were denied access to the data on the operations and sales of the J. & P. Coats firm as a whole, on the ground that any such examination would disclose the company's foreign business and be detrimental to its interests.

UNIVERSITY OF MICHIGAN LIBRARIES

to indicate in a general way the position of Great Britain as a producer of sewing thread. As indicated by Table 8, which shows the exports of cotton sewing thread of Great Britain for 38 years, the quantity of shipments abroad attained the record average of 32,640,000 pounds annually during the 5-year period, 1899–1903. A decline in trade in the following decade brought exports down to 20,730,400 pounds in 1913. In 1916 exports rose to 24,701,800 pounds, the highest volume since 1909. The quantity of exports since the war has been considerably below the pre-war amount. During the five years, 1922–1926, the amount of exports was maintained at practically a stationary level, averaging about 18,000,000 pounds annually. Exports in 1925 represented a value of $36,754,000; in 1926, $34,986,983. As previously mentioned, the J. & P. Coats concern and the English Sewing Cotton Co. export over four-fifths of the goods[25] which they make in their British factories, the major part of their profits being derived from the trade in foreign and colonial markets.

TABLE 8.—*Cotton sewing thread—Exports of the United Kingdom, 1889–1926*

1907	31,726,700	24,062,404	1926	19,048,104	34,986,983

The principal markets for British exports of cotton thread are British India, Argentina, Mexico, Australia, Brazil, and Sweden.

France.—France occupies a position of prominence in the manufacture of fine mending, embroidery, and crochet cottons for handwork. The products of Dollfus-Mieg et Cie., of Mulhouse, the pioneer in the handwork-cotton industry, have already been alluded to in the section on "domestic exports," page 27.

In addition to Dollfus-Mieg et Cie, there are two other internationally known French companies, (1) Cartier-Bresson, Société Anonyme, a century old concern, with factories at Pantin (Seine), Celles-sur-Plaine (Vosges), and Azerailles (Meurthe & Moselle), and (2) Maurice Frings et Cie, Manufacture Parisienne des Cotons L. V. & M. F. A., with establishments at Hellemmes, Lille, and Vitry-sur-Seine.

[25] The directors of the J. & P. Coats (Ltd.) stated to the sewing-cotton investigation committee that during the year ended June 30, 1919, 80.69 per cent of the profit arising from products manufactured in the United Kingdom was derived from sales in the foreign market; in 1914 the percentage was 83.86.

The production of sewing thread and handwork cottons in France is not officially recorded nor are export figures available, since French statistics do not separately enumerate either of these commodities.

Germany.—There are in Germany a number of independent thread concerns not connected with the German Sewing Thread Syndicate. Several of the independent companies are combined for the distribution of their products. The sales organization known as the Deutsche Naehfaden-Aktiengesellschaft, of Hamburg, which supplied exporters of textile goods engaged in trade with eastern and South American markets was involved in bankruptcy proceedings in October, 1925.[26]

Germany normally maintains a favorable export balance in cotton sewing thread. In 1913, German exports of cotton thread of all kinds, put up on wooden spools for the retail trade, amounted to approximately 3,066,000 pounds, valued at $1,268,000. Since the resumption of foreign commerce in 1920, German exports of sewing thread of cotton have been steadily advancing, and in 1923 fell just short of 1,000,000 pounds, the largest amount in the postwar period. In 1924, 1925, and 1926 they declined slightly in quantity from this record, but were, on the other hand, twice as large in value.

Even more important than the trade in sewing thread are the German exports of cotton thread in hanks, skeins, etc., which probably includes the handwork cottons. The 1913 pre-war exports of articles in this category amounted to nearly 5,895,000 pounds, valued at $5,831,000. The heaviest exports since the war occurred in 1923 when shipments totaled 1,590,178 pounds; in 1925, they amounted to 805,600 pounds, valued at about $1,067,000; and in 1926 to 854,000 pounds, valued at $1,161,600.

Other countries.—Austria, Belgium, and Italy are the only other countries of importance in the export trade in cotton thread and yarns for handwork. Shipments from Austria since the war have exceeded by a considerable margin the quantity exported by Austria and Hungary combined immediately prior thereto. In 1913, exports of the dual kingdom amounted to 1,625,011 pounds as compared with the postwar exports of Austria alone which aggregated 2,652,354 pounds in 1923, 2,572,547 pounds in 1924, 2,251,117 pounds in 1925, and 1,794,324 pounds in 1926. Belgian statistics under the caption "cotton yarn prepared for the retail trade" show in 1913 exports of 3,440,000 pounds, valued at $1,593,000. Postwar shipments have been smaller, aggregating 2,918,000 pounds in 1922, 2,664,000 pounds in 1924, and 2,245,000 pounds in 1925. In 1926, they fell off to 1,970,900 pounds, valued at $1,004,499.

The Italian export trade in sewing cotton put up in balls, skeins, or spools for retail trade was comparatively small prior to the war, approximating only 297,000 pounds in 1913. Postwar figures show a considerable expansion, the exports in 1921 exceeding 2,300,000 pounds, valued at $1,967,000. In recent years there has been a slight decline, although exports are still well above the pre-war level. The reverse is true of the trend of imports which have not regained their 1913 volume. Moreover, imports prior to the war were three times as great as exports; in the seven years, 1920–1926, average shipments abroad were more than double in quantity the imports into the country.

[26] *Daily News Record*, Oct. 28, 1925.

UNIVERSITY OF MICHIGAN LIBRARIES

Japan, which exported only about 316,000 pounds of cotton thread in 1913, entered foreign markets on a large scale when European deliveries were at a low ebb during the war. In 1920 Japanese shipments amounted to over 4,276,000 pounds. Although a drastic decline has occurred since that year as a result of the revived trade activities of the former leading exporting countries in cotton thread, the exports of Japan in 1925 totaled 637,400 pounds, or more than twice the volume for 1913. Exports declined still further in quantity in 1926, amounting to 592,866 pounds, valued at $346,800.

From Table 9, which arrays the chief thread-exporting countries according to rank, it may be seen that shipments from the United Kingdom greatly exceed the aggregate exports of all other countries combined. Belgium, Germany, Austria, Italy, and the United States follow in the order named, each exporting over a million pounds of thread and handwork cottons annually.

Table 10 shows the relative standing of the principal thread-purchasing countries, listed in serial order descending according to quantity of imports. The United States is not included in the table, as its statistics of such imports, recorded in yards, are not comparable with the poundage figures of other countries. Omitting the United States, the Far East is the most important market for sewing thread and cottons for handwork, British India taking first rank and China second. Canada and Sweden are the next largest importers. From the standpoint of value, the United States in most years ranks first and British India second as purchasers of thread and handwork cottons. In 1925 imports into the United States amounted to $3,463,960, as compared with imports into British India valued at $2,844,822; China, $1,763,400; Italy, $1,438,324; Canada, $1,319,930; Czechoslovakia, $1,264,650; and Sweden, $1,108,698.

Cotton thread for retail trade	([3])	563,055	401,237	124,560
Cotton knitting and embroidery yarn for retail trade	([3])	291,007	311,951	229,940
Switzerland: Cotton sewing thread made up for retail trade (on reels, in balls, and skeins folded in flat layers, doubled yarn, English knitting yarn, etc.)	398,371	284,482	337,304	346,122
Germany: Cotton thread of all kinds, twisted, made up for retail trade	53,131	302,251	406,308	320,328
Austria: Cotton yarn for retail trade	204,146	183,643	195,328	201,941

[1] Quantity in gross of 12 dozens; pounds not given.
[2] See note 2, p. 33.
[3] Not available.
[4] Loop and fancy yarns included.

IMPORTS

Extent.—Table 11 is a chronological summary of the history of imports for consumption of cotton thread under the acts of 1890 and 1894 and of the inclusive imports of cotton thread and handwork cottons under the acts of 1897, 1909, 1913, and 1922 to the end of the calendar year 1926. There are also shown the revenue collected, the unit values, and the equivalent ad valorem rates of duty.

Under the act of 1890, imports for consumption of "spool thread of cotton" averaged annually 934,371,700 yards, valued at $97,212. Under the act of 1894, when the rate of duty was reduced from 7 cents to 5½ cents per 1,200 yards (12 spools of 100 yards each), imports of thread virtually doubled, averaging annually 1,826,671,000 yards, valued at $170,686.

In the next act, 1897, an eo nomine provision was made for the first time for crochet, darning, and embroidery cottons, mention being made in the same paragraph with cotton thread. Statistics of imports of such cottons for handwork had previously been lumped with cotton yarns. Under that act, however, and also under the two subsequent acts of 1909 and 1913, import figures for handwork cottons were combined with cotton sewing thread imports as inclusive totals. Not until after the passage of the act of 1922 were statistics segregated for each group.

The average annual imports for consumption of cotton thread and handwork cottons combined amounted to 1,576,586,400 yards, valued at $227,620, under the act of 1897; to 4,399,171,000 yards, valued at $1,137,865, under the act of 1909; to 6,696,722,200 yards,

valued at $2,391,429, under the act of 1913; and to 3,320,908,100 yards, valued at $2,942,443, under the act of 1922, to the end of the calendar year 1926.

TABLE 11.—*Cotton sewing thread and cottons for handwork*[1]*—Imports for consumption and revenue, 1891–1926*

Fiscal year (unless otherwise stated)	Quantity	Value	Duty collected	Value per unit	Equivalent ad valorem rate
	100 yds.				*Per cent*
1891 (Oct. 6, 1890, to June 30, 1891)	4,796,736	$55,454	$27,981	$0.012	50.46
1892	9,165,960	100,761	53,468	.011	53.06
1893	10,438,224	107,982	60,890	.010	56.39
1894	10,053,468	95,884	58,645	.010	61.16
1895 (July 1 to Aug. 27, 1894)	1,947,720	18,645	11,362	.010	60.94
Total (1,422 days, act of 1890)	36,402,098	378,726	212,346	.010	56.33
Annual average (act of 1890)	9,343,717	97,212	54,505	.010	56.33
1895 (Aug. 28, 1894, to June 30, 1895)	14,997,385	139,036	68,738	.009	49.44
1896	17,343,162	149,413	79,490	.009	53.20
1897	20,577,889	205,689	94,315	.010	45.85
1898 (July 1 to July 24, 1897)	230,184	2,487	1,055	.011	42.42
Total (1,062 days, act of 1894)	53,148,620	496,625	243,598	.009	49.05
Annual average (act of 1894)	18,266,710	170,686	83,722	.009	49.05
1898 (July 25, 1897, to June 30, 1898)	19,987,716	213,501	99,938	.011	46.81

1926 (calendar year)	22,001,762	2,379,716	477,544	.108	20.07

Imports shown under acts of 1890 and 1894 were listed as "spool thread of cotton." Imports recorded under acts of 1897, 1909, and 1913 include not only spool thread of cotton but also crochet, darning, and embroidery cottons. Imports under act of 1922 were listed as "cotton sewing thread, and crochet, darning, embroidery, and knitting cottons."

[1] Includes 1,765,531,500 yards (283,489 pounds) valued at $992,683, containing cotton of 1⅜ inches or longer paying, under the emergency tariff act, 7 cents a pound in addition to the regular duty of 15 per cent ad valorem; total duty $168,747, equivalent to 17 per cent ad valorem.

[2] Includes 3,910,265,700 yards (651,061 pounds), valued at $2,188,023, subject to emergency tariff act surtax of 7 cents a pound and paying total duty of $373,778, equivalent to 17.08 per cent ad valorem.

UNIVERSITY OF MICHIGAN LIBRARIES

In the acts of 1897, 1909, and 1922 the specific duty amounted to one-half of 1 cent per 100 yards; in the act of 1909 there was a proviso for a minimum rate of 20 per cent ad valorem; this was also retained in the act of 1922 which added, however, a maximum rate of 35 per cent ad valorem. In the act of 1913 the rate of duty was 15 per cent ad valorem. The rates of duty averaged 34.63 per cent ad valorem, or 0.50 cent per 100 yards, under the act of 1897; 23.78 per cent ad valorem, or 0.62 cent per 100 yards, under the act of 1909; 15.30 per cent ad valorem, or 0.55 cent per 100 yards, under the act of 1913; and 20.17 per cent ad valorem, or 1.79 cents per 100 yards, under the act of 1922, to the end of the calendar year 1926. (See Table 21, p. 56.) Of the four tariff acts mentioned it is seen that the act of 1897 carried the highest equivalent ad valorem rate of duty but the act of 1922 the highest equivalent specific duty in cents per 100 yards. The variations between the equivalent ad valorem and the equivalent specific rates are due to variations in the average unit prices and imports under the act of 1922 have been on an unusually high price level.

A consideration of the data presented in Table 11 for the inclusive imports of cotton thread and handwork cottons under the last four tariff acts will show that there are three distinct periods: (1) A period of about eight years, from the beginning of the act of 1897 to the end of the fiscal year 1905, in which imports were small and during most of the time practically stationary; (2) a period of 11 years, the fiscal years 1906 to 1916, inclusive, characterized by rising imports; and (3) a period of 10½ years, from the beginning of the fiscal year 1917 to the end of the calendar year 1926, of declining imports. It is significant that the period of rising imports and the period of declining imports did not begin with tariff acts but occurred at times when no change was contemplated in the existing rate of duty. This would tend to indicate that increases and decreases in the volume of imports of cotton thread and handwork cottons are due more largely to the law of supply and demand than to the tariff law, although changes in the rate of duties may accentuate the trend of imports. Imports under the first eight years of the act of 1897 appear to have been confined mainly to cotton thread and the rise that started in 1906 was apparently due to the inclusion of increasing amounts of handwork cottons. The start of the decline that has occurred since 1916 was probably an effect of war conditions, but its continuance has apparently been due to rising costs abroad and to the increased power of competition of the domestic manufacturers.

Tables 11a and 11b show the segregated statistics of imports of cotton thread and of handwork cottons under the act of 1922, the only period for which they are available. These statistics are given as recorded in Commerce and Navigation of the United States, but there is some doubt as to the correctness of the segregation of the two articles. These data show that imports of cotton sewing thread exceed imports of handwork cottons (crochet, darning, embroidery, and knitting cottons), but the reverse is claimed by importers and by the officials who examine imports. According to the New York examiner, imports of sewing thread are insignificant in quantity, consisting of only occasional shipments of specialties such as glazed thread and thread for mending gloves, etc., and the bulk of the imports under paragraph 902 of the tariff act of 1922 are handwork cottons.

This declaration was substantiated by analysis of the invoices at the customs house. Further confirmation was obtained from importers, and others conversant with the trade, who assert that imports of foreign sewing thread are negligible and that foreign handwork cottons are the only articles of any importance imported under paragraph 902. The 1926 figures, as shown in Tables 11a and 11b, show that imports of cotton thread averaged 10.3 cents per 100 yards and imports of handwork cottons 11.5 cents; the first-named price is apparently much too high for cotton sewing thread and this fact in itself tends to show erroneous segregation. The discrepancy between the recorded data and the facts as revealed by the invoices, the official examiners, and the trade, may arise from the lack of a clear line of demarcation between the words "thread" and "yarn" as used in the trade. Certain kinds of handwork cottons, such as the six-cord crochet and tatting cottons in the finer counts, closely resemble ordinary sewing thread in construction and are often referred to as crochet or lace threads. It is probable that these and other imports have been listed in import statistics as thread, with the result that amounts intended for sewing and the amounts intended for crocheting, darning, embroidering, and knitting, are not correctly differentiated in the records.

[1] Separately recorded prior to act of 1922. Imports here shown are included in Table 11.

—Imports of cotton sewing thread and cottons for handwork recorded as to origin prior to 1918. In 1919, approximately t of the total quantity of imports came from Scotland and per cent from England. In the following year, France the American market, contributing more than 14 per cent

of the quantity and 20 per cent of the value of imports from all countries. The heaviest imports of French thread and handwork cottons occurred in 1923 when shipments aggregated 3,114,500,800 yards valued at $2,726,160, representing more than 73 per cent of the total volume and 85 per cent of the value. In quantity the quota supplied by France since 1923 has been declining both absolutely and relatively, amounting to 1,317,581,700 yards in 1926 or 60 per cent of the aggregate. This downward trend, on the other hand, has not been evidenced in the value of French shipments, which in 1925 reached the peak figure of $3,014,274 or nearly 87 per cent of the value of all thread imported. Coupled with the diminished quantity, this represents a striking increase in the unit value of the goods. Whereas the average unit value of French imports amounted in 1923 to $0.087 per hundred yards, this rose in 1924 to $0.105 and in 1925 to $0.142. Although the value of the imports from France fell in 1926 to $1,909,333, the average price per unit of 100 yards slightly increased to $0.144.

Table 12a shows the percentages of the total imports of cotton sewing thread and handwork cottons contributed by the five chief suppliers of the United States from July, 1918, to December 31, 1926. The figures on which these computations are based are presented in Table 12 which gives the general imports by quantity and value for this period.

In reading import statistics in Table 12, it should be borne in mind that merchandise landed in the United States may be immediately entered for consumption and the importer may take possession after payment of duty, or it may be stored in bonded warehouses. In the latter case the duty is not paid nor are the goods recorded as entered for consumption until such time as they may be withdrawn from the warehouse. Transit trade is not included in ordinary import and export records. Statistics of general imports record, by countries of origin, all merchandise other than that in transit which arrives in the United States, whether duty is paid at the time of arrival or deferred, while statistics of imports for consumption record only merchandise actually taken possession of by the importer. The merchandise recorded in the statistics of imports for consumption may have arrived during the year or a portion may have arrived in a previous year and have just been withdrawn from warehouse. For these reasons, imports for consumption and general imports do not coincide, for any particular year, in either quantity or value. The difference between the two in any one year is the measure of the variation in level of the stock of the commodity in bonded warehouses. In some years more is put into bonded warehouses than is withdrawn, thus causing imports for consumption to be less than general imports. An excess of imports for consumption usually indicates strong demand.

New York is the principal customs district for the entry of imports of sewing thread and handwork cottons; Porto Rico ranks second, and Chicago third.

[2] Figures for United Kingdom.

Type and quality.—The unit value of imports under paragraph 902 of the act of 1922 averaged $0.076 per hundred yards in 1923; $0.083 in 1924; $0.116 in 1925; and $0.108 in 1926. The high average unit value is, as previously stated, an indication that imports are mainly handwork cottons.

The most popular item imported is pearl cotton (coton perlé) in skeins and balls. (See p. 11.) Next in importance is the stranded cotton (coton mouliné) put up in short skeins of 8.7 yards. Third in popularity is the 6-cord cotton (cordonnet) in large and small balls. The "D. M. C." cottons of the Dollfus-Mieg Co., of Alsace, constitute the greater proportion of these imports. There are also considerable imports of high-grade mercerized mending cottons from other French concerns. In addition to the large imports of the items named above, there are occasional shipments from England of Turkey-red yarn in hanks, and small-lot imports of German couching floss. The relative importance of the import trade of the various types of hand-

work cottons is subject to change, as shifting styles cause fluctuations in demand.

An indication of the high price and inferentially of the high quality of imports is afforded not only by the average annual unit values above noted, but also by the fact that on over 82 per cent of the shipments coming in from abroad, the specific duty of one-half cent per hundred yards is inoperative. That is to say, in relation to the value of the goods, the specific rate is not equivalent to the minimum duty of 20 per cent ad valorem, provided for in paragraph 902. The great proportion dutiable at the minimum rate is significant of the predominance of high-valued goods in the import trade in this trade. This is discussed in further detail in the section on tariff considerations, page 59.

Relation of imports to domestic production.—No accurate comparison of imports with domestic production can be made because of the difference in classification and quantity units used in the statistics of the Census Bureau and of the Bureau of Foreign and Domestic Commerce. Import statistics are reported in yards, production statistics in pounds. Moreover, in the census reports, as noted on page 21, production statistics are available only for "thread," those for handwork cottons being combined with the figures for cotton yarns. Import statistics, however, reflect the classifications of the successive tariff acts which from 1897 to 1922 bracketed cotton sewing thread and cotton handwork yarns in one category. Since import statistics for handwork cottons have been segregated from sewing thread only since the passage of the act of 1922, it is not feasible to compare the value of imports with the value of production prior to the census of 1923. In that year, imports of cotton sewing thread were 4 per cent of the value of such thread produced in the United States; in 1925, approximately 5 per cent. The ratio of the quantity of sewing thread imported to that produced can only be roughly approximated by converting the production in 1923 to yards on the basis of 10,080 yards to the pound (representing a 36/3 cord thread, a reasonable average of the annual production). The result shows the volume of foreign shipments of sewing thread to this country to be only slightly more than 1 per cent of the American production in 1923, and to less than 1 per cent in 1925. At best, however, comparison of the relation of imports to production is unsatisfactory when on a value basis, since, as was pointed out in the preceding paragraphs, import statistics of sewing thread are unduly swelled by the addition of a large proportion of handwork cottons improperly classified as "thread." This limitation should be borne in mind, therefore, in interpreting Table 13.

Cotton sewing thread—Relation of imports to production, 1923 and 1925

UNIVERSITY OF MICHIGAN LIBRARIES

Comparison of imports and exports.—Table 14 presents comparative statistics of imports and exports since 1918. Prior to July 1, 1918, the export trade was not recorded. Comparison can be made only on the basis of value as imports are compiled in yards and exports in pounds.

TABLE 14.—*Cotton sewing thread, and crochet, darning, and embroidery cottons—Comparison of value of imports and exports, 1919–1926*

Calendar year	Imports for consumption	Domestic exports	Excess of exports over imports[1]
1919	$1,851,957	$4,367,762	$2,515,805
1920	3,402,142	4,471,617	1,169,475
1921	1,920,125	2,055,328	135,203
1922	2,742,379	2,084,732	−707,647
1923	3,176,176	2,065,520	−1,110,656
1924	3,036,175	1,772,668	−1,263,507
1925	3,463,960	1,183,347	−2,280,613
1926	2,379,716	1,439,862	−939,854

[1] A minus sign indicates excess of imports over exports.

The high value of exports in 1919 and 1920 as compared with subsequent years was due in part to inflated prices but in larger part probably to the opportunity afforded domestic producers by the restriction of European exports during the war and the early postwar period. Following the recuperation of the industry abroad, the net balance of trade of the United States in sewing thread and handwork cottons has ceased to be in favor of exports. For the last five years imports have been the larger. The margin between imports and exports, which had been steadily rising since 1922, amounted to $2,280,613 in 1925, but declined in 1926 to $939,854.

PRICES

Trend of domestic prices of sewing thread, 1890–1926.—The domestic price of 6-cord sewing thread in 200-yard spools, at wholesale, was 3.2 cents per spool in 1890. It remained practically stationary at this point for a decade, undergoing but two slight reductions of a fraction of a mill per spool during the 10-year period. In 1900 the price was advanced to 3.7 cents per spool of 200 yards, at which it remained for nearly seven and one-half years. A rise to 4.5 cents occurred in June, 1907, followed by a decline in March and another in November, 1908, when the wholesale price dropped to 3.9 cents. It remained at this level until lowered to 3.6 cents in July, 1914, just before the outbreak of the World War. This price was in effect until July, 1916, when the upward movement began. Following an advance in November, 1916, to 3.8 cents, it rose in August, 1917, to 4.9 cents, at which it stood for over a year. After two price increases in the latter part of 1918, three upward changes in 1919, and monthly rises in the first quarter of 1920, the peak of 11.7 cents was reached in March, 1920. In the next month, April, there was a sharp decline to 9.3 cents. After two subsequent reductions, the price in August, 1921, reached 5.8 cents, which was in effect for nearly three years. In May, 1924, the price per 200 yards advanced to 6.8 cents and in the following month to 7.3 cents, at which level it has since remained. The monthly wholesale prices and the average for each year from 1890 are presented in Table 16, page 43.

Table 15 summarizes the annual average prices from 1890 to 1926, the relative price on the basis of the 1913 price, and presents for comparison the general index of prices in all commodity lines.

Average annual wholesale and relative prices of cotton thread, 6-cord spools, J. & P. Coats, compared with all-commodities index, 1890–1926

UNIVERSITY OF MICHIGAN LIBRARIES

The prices noted in the above tables are based throughout on the 200-yard spool, which was the standard form for household use until January 12, 1917. On that date occurred the first change in yardage. Black sewing thread was reduced to 150 yards and colored to 100 yards. The yardage of white thread, which at that time was unaffected, was later reduced to 150 yards on August 1 of the same year. On November 2, 1919, white and black threads in sizes 40 and finer were reduced to 100 yards per spool; in sizes below 40 the 150-yard put-up was retained. At this time a 250-yard dressmaker's size spool was introduced in this size range. The 150-yard length was replaced on the market for white and black thread in August, 1921. In the next change, which occurred on May 12, 1924, the entire line of sewing thread for household use, including white, black, and colors, was put up in 100-yard spools. The dressmaker's 250-yard spool was discontinued by one of the large companies but retained by the other.

The wholesale value of cotton sewing thread in 1925 and 1926 was 86 per cent higher than the pre-war level. At the peak of inflation sewing thread rose 149 per cent above the normal average of 1913. As indicated by the table, prices of sewing thread normally exceed the general average of wholesale prices on all commodity lines. From 1892 to 1913 they were steadily higher. During the war years, 1914–1919, however, the reverse was true. In 1920 and 1921 the relative price of sewing thread again exceeded the index number for wholesale prices. While it was about on a par with the general price level in 1922, and slightly less in 1923, it again rose in 1924, 1925, and 1926 to a point above the average of all commodities. Prices of sewing thread averaged higher in 1925 and 1926 than in any previous year except 1920.

It may be noted that in 1922 and 1923 prices of sewing thread were lower than in the three subsequent years in spite of the duty on raw cotton having a staple of 1⅜ inches or more in length, which was imposed by the emergency tariff act, effective from May 28, 1921, to September 21, 1922, inclusive. A considerable part of the raw cotton used in the sewing-thread industry is the long-staple Egyptian cotton dutiable under that act. The price of the finished sewing thread did not reflect at that time, nor in the following year, any increase in the cost of the raw material resulting from this tariff, as a depression then prevailed in the world market for long-staple Egyptian cotton which brought prices to a low level as compared with the three following years.

Prices of domestic sewing thread on spools for household use are uniform as to territory and uniform as to buyers, differing only with regard to discounts on the size of the order. The custom among manufacturers of household spool thread is to have one list price for wholesalers and jobbers, another for small retailers, and a third for the large retailers who contract for the minimum amount of 750 dozen spools on the "purchase order" plan. One of the trio of large manufacturers has also a series of discounts for purchase orders of 500 dozen and 250 dozen.

Prices of sewing thread to wholesalers and jobbers are not in alignment in the schedules of the two largest companies, the American Thread Co., and the Spool Cotton Co., which is the selling organization of J. & P. Coats, the Clark Thread Co., and the Clark

Spool Cotton Co. The Spool Cotton Co. maintains a
e level than does its chief competitor, the American
., a fact largely attributable to the prominence and tra-
stige of its brands in the field of household thread pro-
Moreover, it requires a shipment of at least 100 dozen
ivilege of freight prepayment. The American Thread
other hand, allows freight on shipments of 25 dozen or
prices of smaller and less well known manufacturers of
hread are in most instances lower than the quotations of
e above.

domestic and foreign handwork cottons.—As the chief
ler paragraph 902 of the act of 1922 are the crochet and
cottons for handwork, prices have been compiled for the
tant types of imports of the French D. M. C. cottons and
prices for competing domestic lines. These are pre-
ables 17, 18, and 19. It is evident from these tables that
f the products of the Dollfus-Mieg Co., of France, are
every instance than the comparable American-made
However, the French imports have, in general, a larger
ball or skein per number, indicating a finer grade of
, and for that reason would logically command higher
D. M. C. cottons, moreover, are made in a greater
olors, a wider assortment of sizes, and a more extensive
s in colors. The American-made products have usually
e price quotation for the entire range of sizes and colors,
D. M. C. cottons in certain types vary in price according
ss of the yarn size. Moreover, they have for the most
ies of prices—one for white and ecru, another for black
The retail price of the D. M. C. cottons, however, is

[illegible]IVE CONDITIONS

[illegible] most important producer of cotton [illegible] purveyor of thread in the world's [illegible] source of imports into this country. [illegible] United States, however, is virtually [illegible] as the volume of incoming shipments [illegible] greatly surpassed in recent years by the [illegible] cottons for crocheting, mending, and [illegible] now constitute the bulk of the imports [illegible] of the tariff act of 1922.

[illegible] the domestic sewing-thread market has [illegible] international control of the world's thread [illegible] which have extensive branch holdings [illegible] well-defined export markets in those coun- [illegible] have not been established. The out- [illegible] & P. Coats, and its subsidiary, the Clark [illegible] have had affiliated branches in this country [illegible] while the English Sewing Cotton Co., the [illegible] Britain, has maintained interests here for [illegible] century. The production of household sewing [illegible] cottons by the three companies of the United [illegible] owned stock amounts, it is estimated, to about [illegible] domestic output. The dominant position [illegible] in the field of household spool-thread produc- [illegible] factor accounting for the comparatively small [illegible] thread exported to the United States by the two [illegible] concerns in England and Scotland.

[illegible] of crochet and embroidery cottons for hand- [illegible] eminence has been held by France for generations. [illegible] advantage of the two French companies, Dollfus- [illegible] Cartier-Bresson Société Anonyme, particularly the [illegible] result of over a century of skill in the manufacture of [illegible] yarns for needlework craft and their efficiency in the [illegible] distribution of their goods.

[illegible] French handwork cottons are essentially a quality [illegible] before the war they surpassed the American-made articles [illegible] silklike finish, the extent of color range, fastness of [illegible] of yarn count. The American market had been so [illegible] dominated by the French imports that it was extremely [illegible] handwork cottons of domestic manufacture to displace [illegible] the esteem of customers. When imports from France were [illegible] during the war, it became clearly manifest that domestic [illegible] were extending their output and successfully bidding for [illegible] patronage. A few concerns lost the trade when imports [illegible] from their former source after the end of the war. [illegible] the manufacturers who had obtained a firm hold on the [illegible] during the absence of French competition have continued [illegible] in a strong position owing to the greatly improved quality of [illegible]

[illegible] present-day volume of sales of domestic-made handwork [illegible] greatly exceeds the pre-war turnover. Coincident with the [illegible] advance in quantity, there has been a noteworthy progress [illegible] the betterment of the quality of the product. The utilization of [illegible]

e extensive range of dyes and higher types of cotton
rcerizing properties has enhanced the relative competi-
the majority of the American mills until now their
es favorably with the imported French goods. More-
usness of import deliveries has given the American
considerable advantage, because of the proximity of
l their readiness to fill orders with dispatch. Further-
of the French handwork cottons is generally higher
mestic articles of similar type. This, however, does
have an adverse effect on the consumption of the
by that element of the public which prefers such yarns.
growing ability of American producers of handwork
pete with the French, it is probable that the latter
lead in certain lines of handwork cottons made of
yarns which are not produced on a commercial scale

TARIFF CONSIDERATIONS

iff legislation.—Cotton sewing thread was included
rn in the tariff act of March 2, 1861, under the
'spool and other thread of cotton", with a duty of 30
lorem. This was raised in 1862 to 40 per cent ad
64 cotton sewing thread received separate recogni-
t time, the rate then levied being 6 cents per dozen
rds each, or fraction thereof, and in addition thereto
valorem. The tariff act of the following year, 1865,
ne specific duty, but made the ad valorem part of
uty 30 per cent on spools of not over 100 yards and
pools of more than 100 yards. These rates, which
ged in the tariff of 1870, were reduced by 10 per
l restored in 1875 to the level of the tariffs of 1865

83 substituted for the compound duty a straight
cents per dozen spools for each 100 yards or fraction
te was carried over in 1890 but subsequently reduced
er the act of 1894.
ing, and embroidery cottons were added to the
pool thread in the act of 1897. Their exclusion
aragraph was due in part to the fact that their
itrary and not in strict accord with the system of
for yarns for textile manufacturing. They are
small balls or skeins in a large number of varieties
er trade-marked brands and names rather than by
yarn of which they are made. Hence, any attempt
arn number for the purpose of levying tariff duties
nts, as on ordinary cotton yarns, would entail great
ficulties which are avoided by the flat specific rate.
the duty on both cotton sewing thread and crochet,
broidery cottons was again raised to 6 cents per
eels of 100 yards or fraction thereof. The para-
rther for thread and handwork cottons otherwise

than on spools or reels; for such it levied a duty of one-half of 1 cent for each 100 yards or fraction thereof.[27]

It was prohibited for the first time in the act of 1897 to assess the duty upon a fewer number of yards than that marked on the spools or reels. This proviso was framed to induce agreement between the actual contents of the spools, reels, balls, etc., and the quantity indicated thereon. Overstatement of quantity by the manufacturer would thus become unprofitable to the producer, since he would be obliged to pay the duty on the number of yards indicated on the container and would, therefore, derive no advantage from exaggerating the yardage unless the value of the thread not delivered was equal to the duty on the same shortage of yards.

In 1909 the specific rates of the preceding act on sewing thread, crochet, darning, and embroidery cottons were maintained, a proviso being added that the rate should in no case be less than 20 per cent ad valorem. No limit was specified as to the length of the thread and yarns contained on the spools, reels, or balls. However, if the thread or yarn entered in the form of skeins, cones, or tubes, the maximum length was restricted to 600 yards. If the yardage exceeded this figure, the threads and handwork cottons were to be assessed as yarns under the cotton-yarn paragraph in the law. The purpose of this length limitation was to clarify the ambiguity of wording in the tariff act of 1897. Although it was the evident intention of Congress to include only yarns for hand use, litigation resulted over the scope and meaning of the term "embroidery cotton" in that act. Under the decision of the United States Circuit Court of Appeals, second circuit, 1906, it was ruled that "embroidery cotton" was a well-known commercial term in the trade which referred then only to that which was used in hand embroidery and put up in short skeins. It was held, therefore, that yarn put up on paper bobbins for use on embroidery machines did not come within the class of embroidery cottons.[28] (*Loeb* v. *United States*, 150 Fed. 327.) The Board of General Appraisers in G. A. 6730, T. D. 28803, followed this ruling and held that embroidery cotton imported in large skeins containing 15,000 to 21,000 yards, though identical to that put up in small skeins and boxed, was not dutiable as embroidery cotton but as cotton yarn. In the framing of the act of 1909 cognizance was taken, therefore, of the legal decisions which interpreted the 1897 provision as applying solely to yarns for handwork. The insertion of the length limitation thus made any other interpretation impossible.

A flat 15 per cent ad valorem duty was substituted in the act of 1913 for the specific rates, on spool cotton and crochet, darning, and embroidery cottons, irrespective of finish, count, method of manufacture, and put-up. This act omitted specifying a maximum yardage for yarns coming in under the paragraph. As a result of the deletion of this clause, the paragraph was again involved in litigation. The United States Court of Customs Appeals in 7 Ct. Cust. Appls. 414, held that the term "embroidery cottons" in the paragraph in

[27] In the opinion of the Board of Appraisers (G. A. 4061, T. D. 18748), the language "otherwise than on spools or reels" might fairly be rendered "thread in bulk." It decided that the expression "one-half of 1 cent for each 100 yards or fractional part thereof" meant that the aggregate number of yards in the invoice must be ascertained and not that if each skein contains less than 100 yards it must be taxed as if contained 100 yards at one-half cent per skein, the words "fractional part thereof" referring to the fractional part of 100 in the total number of yards.

[28] The Treasury Department construed and applied the law in accordance with the Loeb case up to 191

oidery cottons, irrespective of whether intended for hand
. This decision was based on the hypothesis that Con-
ting embroidery machines free under the act of 1909

courage the domestic embroidery industry both hand
Hence, it was believed that it was the congressional
or one of the necessary materials for the infant in-
embroidery cottons," with a comparatively low rate
void setting at naught what was thus interpreted to
f Congress, embroidery cottons for machine use were
it of the statute by the courts and were held entitled
levied on special handwork cottons.

liminate the discriminatory classification of one type
is favored merely on the basis of intended use and not
essential particular from ordinary yarns for knitting,
ng, and other textile manufacture, the length limita-
d in the act of 1922. While the act of 1909 limited
0 yards, the 1922 act put the point of delimitation at
he ground that the latter more nearly represents the
m length of cottons sold for the retail trade. This
the purview of the paragraph only yarns intended
ince yarns for machine work are as a rule of greater
re economy in production. As a final precaution a
for handwork" was added to definitely establish the
f yarns for machine embroidery under the paragraph
ine yarns.

922 the term "cotton sewing thread" was substituted
'spool thread of cotton," owing to the anomalous
r appellation for sewing thread not on spools nor
ls. The term "spool thread" had been in continuous
ince 1861. Imports at that time were for the most
out as the industry progressed thread was put up
n skeins and in the form of tubes, cones, and large
for consumption by manufacturers. Since the
rued "spool cotton" to include also unfinished and
d in skeins, which was intended for use as sewing
completed was suitable for such (T. D. 37793–G. A.
eld illogical to continue a term that had become
he elimination of the word "spool" it was also
ention the form of put-up, since sewing thread is
ardless of the manner of winding or the form of the
s wound.

ochet, darning, and embroidery cottons was added
otton which logically belongs to the group of hand-
th similarity and use. Sewing thread and cottons
er the act of 1922 were subjected to the same rate
amely, one-half cent per 100 yards. A provision
ig a minimum duty of 20 per cent and a maximum
t ad valorem.

he last six tariff acts.—Table 20 shows the total
mption of cotton sewing thread and cottons for

609–T. D. 17435, G. A. 4674–T. D. 22080, T. D. 30184–G. A. 6952.

handwork and the duty collected thereon for each inclusive period covered by the last six tariff acts. For comparative purposes, these data are reduced to a uniform basis of 365 days in Table 21, which also gives the average annual unit value and the average specific and ad valorem rates of duty under each act.

TABLE 20.—*Total imports for consumption of cotton sewing thread and cottons for handwork* [1] *under each of the last six tariff acts*

Act of—	Inclusive period	Number of days	Total quantity imported	Total value	Total duty collected
			100 yards		
1890	Oct. 6, 1890, to Aug. 27, 1894	1,422	36,402,098	$378,726	$213,346
1894	Aug. 28, 1894, to July 24, 1897	1,062	53,148,620	496,626	243,598
1897	July 25, 1897, to Aug. 5, 1909	4,394	189,795,084	2,740,168	948,974
1909	Aug. 6, 1909, to Oct. 3, 1913	1,520	183,198,355	4,738,508	1,127,041
1913	Oct. 4, 1913, to Sept. 21, 1922	3,275	600,870,281	21,457,341	3,284,020
1922	Sept. 22, 1922, to Dec. 31, 1926	1,562	142,116,668	12,592,044	2,540,152

[1] Crochet, darning, and embroidery cottons included only since July 24, 1897.

Act of—	Annual average			Average value per 100 yards	Equivalent ad valorem rate	Equivalent specific rate per 100 yards
	Quantity	Value	Duty			
	100 yards				*Per cent*	*Cents*
1890	9,343,717	$97,212	$54,505	$0.010	56.33	0.58
1894	18,266,710	170,686	83,722	.009	49.05	.46
1897	15,765,864	227,620	78,829	.014	34.63	.50
1909	43,991,710	1,137,865	270,638	.026	23.78	.62
1913	66,967,222	2,391,429	366,005	.036	15.30	.55
1922 [2]	33,209,081	2,942,443	598,569	.089	20.17	1.79

[1] The yearly figures from which these two tables are calculated are shown in Table 11 on p. 35.
[2] To Dec. 31, 1926.

As previously noted, the difference in tariff wording and the legal interpretation thereof have caused differences in the composition of the imports recorded for the various acts in Tables 20 and 21. Imports shown for the acts of 1890 and 1894 relate to cotton sewing thread exclusively, whereas those under subsequent acts embrace cotton sewing thread and handwork cottons. The imports shown for the act of 1913, moreover, include also embroidery yarns for machine work. The volume of such yarns imported during this period and lumped with handwork cottons in the statistical records can not be determined, but it was undoubtedly large, because the domestic machine embroidery industry was then in the early stages of its development and dependent to a more or less degree upon foreign sources of supply.

It may be observed from Table 21 that in value the average annual imports were lowest under the act of 1890 and have increased under each successive act up to and including that of 1922. This steady rise in value has been due in large part to the upward trend of the average unit value per 100 yards. In quantity, on the other hand, the average annual imports show fluctuating tendencies, alternately expanding and declining under the acts of 1894 and 1897, successively

under the next two acts, 1909 and 1913, and decreasing
ıg the period of the present tariff act. It is important to
hat a part of the record growth of the trade in thread and
cottons indicated by the import statistics for the act of
to a certain extent fictitious, inasmuch as the inclusion
; act of embroidery yarns for machine work was a strong
welling the quantity of the average annual imports. Their
ınder the act of 1922, on the other hand, was a factor in the
ecorded for the subsequent period. Such differences in the
on of the imports tend to obscure somewhat the results of
in the rates of duty upon the volume of trade.

idering the effect of tariff changes on quantity of imports,
be noted that the equivalent ad valorem rate of duty,
s 56.33 per cent under the act of 1890, was successively
er the acts of 1894, 1897, 1909, and 1913. Because of rising
es, however, there was no marked change in the equivalent
uty which was under each of these five tariff acts not far
-half of 1 cent per 100 yards. Under the act of 1922, an
ented situation has arisen. Although the equivalent ad
rate of duty is lower than that under any of these acts
13, the unusually high unit value has resulted in an equiva-
ific duty, in cents per hundred yards, which is more than
es that of the average under the five preceding acts.

ecrease in the rate of duty in the act of 1913 apparently
o prolong the cycle of rising imports which began in 1906
e rates of the act of 1897. Likewise, the increase in the
ties on cotton thread and handwork cottons in the act of
ningly stimulated the trend toward a decline in imports that
ed in 1917 under the 1913 rates. As neither of the years
itiated the periods of rising and falling imports were coinci-
h any tariff change, it would appear that the volume of
has been influenced in the long run more by supply and
than by the rate of duty.

tion of the act of 1922.—The tariff act of 1922, like that of
ıposed on cotton sewing thread and on handwork cottons a
duty of one-half of 1 cent per 100 yards, and provided that
the foregoing should pay less than 20 per cent ad valorem.
ariff act of 1922 it was also provided that none of the foregoing
pay more than 35 per cent ad valorem.

ıe basis of unit values per 100 yards, the rates of duty on cotton
thread and handwork cottons in paragraph 902 of the act of
ay therefore be divided into three classes, as follows:

Imports valued at—	Dutiable at—
n 1¾ cents per 100 yards	35 per cent ad valorem.
to 2½ cents per 100 yards	½ cent per 100 yards.
an 2½ cents per 100 yards	20 per cent ad valorem.

seen that the specific duty of half a cent per 100 yards is
e only on imports valued at 1¾ cents to 2½ cents per 100
At the level of prices that have prevailed under the act of
ıt least to the end of the calendar year 1926, the specific rate
ly inoperative, and the great bulk of the imports, being valued
e than 2½ cents per 100 yards, have been dutiable under the
um rate of 20 per cent ad valorem. Table 22 shows the ratio
imports in each value class to the total imports under paragraph
the act of 1922 to the end of the calendar year 1926.

TABLE 22.—*Cotton sewing thread and handwork cottons—Proportions of total imports assessed at the specific, the minimum ad valorem, and the maximum ad valorem rates of duty provided in the act of 1922*

1922, inclusive. [2] Total period from Sept. 22, 1922, to Dec. 31, 1926, inclusive.

The foregoing table shows that imports of cotton sewing thread and handwork cottons under the act of 1922, to the end of the calendar year 1926, averaged 8.86 cents per 100 yards. The ineffectiveness of the specific rate of one-half cent per 100 yards is shown by the fact that without the minimum and maximum ad valorem rates the specific rate would have been equivalent to 0.5 divided by 8.86, or only 5.64 per cent ad valorem.

Comparison of duties on cotton sewing thread and on cotton yarn.—For the purpose of comparing the duties levied on cotton sewing thread with the duties levied on the yarn of which the thread is made, Table 24 has been compiled, giving the tariff rates on representative numbers of 6-cord spool cotton and on the yarns used in their manufacture.

TABLE 25.—*Comparison of tariff rates on 6-cord cotton sewing thread and on yarn used in its manufacture*

Thread ticket No.	6-cord thread			Combed cotton yarn used in 6-cord thread		
	Number of yards to the pound	Specific duty per pound	Minimum ad valorem rate	Yarn No.	Specific duty per pound	Minimum ad valorem rate
		Cents	*Per cent*		*Cents*	*Per cent*
16	4,480	22.4	20.00	32	8.00	18.00
20	5,600	28.0	20.00	40	10.00	20.00
24	6,720	33.6	20.00	48	12.40	22.00
30	8,400	42.0	20.00	60	16.00	25.00
36	10,080	50.4	20.00	72	19.00	28.00
40	11,200	56.0	20.00	80	22.00	30.00
50	14,000	70.0	20.00	100	28.00	30.00
60	15,400	77.0	20.00	110	31.00	30.00
70	16,800	84.0	20.00	120	34.00	30.00
80	18,200	91.0	20.00	130	34.00	30.00
90	21,000	105.0	20.00	150	34.00	30.00

A 6-cord thread of a ticket No. 30, made nominally from six strands of a No. 60 yarn, would run 8,400 yards to the pound. On the basis of a specific duty of half a cent per hundred yards, a pound of a 6-cord No. 30 thread would be dutiable at 42 cents. The specific duty on the combed No. 60 yarn entering into the manufacture of this 6-cord thread of ticket size 30 is according to the provisions of paragraph 901, 16 cents a pound.[30] The specific duty on the 6-cord thread is, therefore, over two and one-half times greater than on the yarn. This ratio between the specific duty on the thread and the yarn entering into its manufacture is maintained approximately throughout almost the entire range of yarn counts.

The relationship between the minimum ad valorem duties on the 6-cord thread and the yarn of which it is made is, on the other hand, variable. The ad valorem duties on the cotton yarn are progressively graduated for all counts up to 80, above which point they are fixed at 30 per cent. On thread there is but one minimum ad

[30] PAR. 901. * * * Cotton yarn, including warps, in any form, bleached, dyed, colored, combed, or plied, numbers not exceeding number 40, one-fourth of 1 cent per number per pound; exceeding number 40 and not exceeding number 120, 10 cents per pound and, in addition thereto, three-tenths of 1 cent per number per pound for every number in excess of number 40; exceeding number 120, 34 cents per pound: *Provided*, That none of the foregoing, of numbers not exceeding number 80, shall pay less duty than 10 per centum ad valorem and, in addition thereto, for each number, one-fourth of 1 per centum ad valorem; nor of numbers exceeding 80, less than 30 per centum ad valorem: *Provided further*, That when any of the foregoing yarns are printed, dyed, or colored with vat dyes, there shall be paid a duty of 4 per centum ad valorem in addition to the above duties.

ıte, 20 per cent, applicable to all ticket numbers. The ad valorem duty on yarn of 32 count, taken for illus- 18 per cent, whereas that for the 6-cord thread made of is 20 per cent. In this instance both the specific and ad ıties on the thread exceed those on the yarn entering into cture. This is true of all threads and cottons made from w No. 40. At this point the ad valorem duties on the ɔduct and the primary yarn coincide. Above No. 40, which the practical limit of yarn of short staple cotton, the ty is less but the minimum ad valorem is more on yarns reads.

ı the minimum ad valorem for yarns above 40s is greater orresponding duty on thread, in actual dollars and cents, ıe duty is considerably less. Owing to the greater amount volved in the advancement of yarn into thread, the invoice read is generally more than twice as great as the average ue of the yarn from which it is made. Hence, in the t of tariff rates on the ad valorem basis, the equivalent, in pound, of the 20 per cent duty assessed on the thread ceeds by a large margin the equivalent, in cents per pound, er ad valorem duty of 30 per cent levied on the less costly s is illustrated in the following table, which compares the ies on cotton sewing thread and the yarns used in its re.

TABLE 27.—*Cotton sewing thread and crochet, darning, and embroidery cottons—Rates of duty, 1883–1922* [1]

Act of—	Paragraph	Tariff classification or description	Rate of duty
1883	326	Spool-thread of cotton, * * *, containing on each spool not exceeding one hundred yards of thread.	7 cents per dozen spools.
		Exceeding one hundred yards on each spool, for every additional one hundred yards of thread or fractional part thereof in excess of one hundred yards.	7 cents per dozen.
1890	343	Spool-thread of cotton, containing on each spool not exceeding one hundred yards of thread.	7 cents per dozen.
		Exceeding one hundred yards on each spool, for every additional one hundred yards of thread or fractional part thereof in excess of one hundred yards.	7 cents per dozen spools.
1894	251	Spool thread of cotton, containing on each spool not exceeding one hundred yards of thread.	5½ cents per dozen.
		Exceeding one hundred yards on each spool, for every additional one hundred yards of thread or fractional part thereof in excess of one hundred yards.	5½ cents per dozen spools.
1897	303	Spool thread of cotton, including crochet, darning, and embroidery cottons on spools or reels, containing on each spool or reel not exceeding one hundred yards of thread.	6 cents per dozen.
		Exceeding one hundred yards on each spool or reel, for every additional hundred yards or fractional part thereof in excess of one hundred.	6 cents per dozen spools or reels.
		If otherwise than on spools or reels	One-half of 1 cent for each 100 yards or fractional part thereof.
		Provided, That in no case shall the duty be assessed upon a less number of yards than is marked on the spools or reels.	
1909	314	Spool thread of cotton, crochet, darning, and embroidery cottons, on spools, reels, or balls, containing on each spool, reel, or ball, not exceeding one hundred yards of thread.	6 cents per dozen
		Exceeding one hundred yards on each spool, reel, or ball, for every additional hundred yards or fractional part thereof in excess of one hundred.	6 cents per dozen spools, reels, or balls
		If in skeins, cones, or tubes, containing less than six hundred yards each.	One-half of 1 cent for each 100 yards or fractional part thereof.
		Provided, That in no case shall the duty be assessed upon a less number of yards than is marked on the spools, reels, cones, tubes, skeins, or balls: *And provided further*, That none of the foregoing shall pay a less rate of duty than	20 per cent ad valorem
1913	251	Spool thread of cotton, crochet, darning, and embroidery cottons, on spools, reels, or balls, or in skeins, cones, or tubes, or in any other form.	15 per cent ad valorem
1922	902	Cotton sewing thread	One-half of 1 cent per 100 yards.
		Crochet, darning, embroidery, and knitting cottons, put up for handwork, in lengths not exceeding eight hundred and forty yards.	One-half of 1 cent per 100 yards.
		Provided, That none of the foregoing shall pay a less rate of duty than	20 nor more than 35 per cent ad valorem.
		In no case shall the duty be assessed on a less number of yards than is marked on the goods as imported.	

[1] "Crochet, darning, and embroidery cottons" were first mentioned in the act of 1897; in previous acts they were dutiable, without specific mention, as cotton yarn.

COURT AND TREASURY DECISIONS RELATING TO COTTON THREAD AND HANDWORK COTTONS

Specific provision was made for crochet cottons, with darning and embroidery cottons, in the act of 1897. The entire clause became involved in litigation. In *Calhoun* v. *United States* (99 Fed. 424) the dutiable length of darning cotton in four 2-ply strands slightly twisted, in balls, was declared to be the length of the cotton in the condition in which imported and not the aggregate length of the strands composing it. The Board of General Appraisers followed this decision in a case upon darning and embroidery cottons (G. 4817, T. D. 22649 of 1900).

United States (150 Fed. 327 of 1906, reversing 143 Fed.
the term "embroidery cotton" was found by the Circuit
peals for the Second Circuit to have, when the act of 1897
a well-known commercial meaning excluding 5-ply yarn
per bobbins and universally wound and used on machines
ing. The proper classification was held to be as yarn.
clared that under the law use was not the test. This deci-
lied by the Board of General Appraisers under the act of
yarn used on embroidery machines to lock the stitch on
. A. 6544, T. D. 27915); to yarn in skeins from 15,000
ds each (G. A. 6730, T. D. 28803, overruling G. A. 5372,
upon thread in large skeins of about 72 inches perimeter
t; to yarn in small skeins labeled "embroidery floss"
T. D. 26070), and to similar merchandise under the act
tracts 26633, T. D. 31883 and 36780, T. D. 34871).
isions limited "embroidery cotton" to hand embroidery
l skeins.
t conclusion was reached by the Court of Customs
later decision. The rate of duty on embroidery cotton
ıan the rates on yarn in the act of 1897, under which the
, supra, was made. This decision was reversed in 1913.
f embroidery machines for a time under the act of 1909
ve an impetus to machine embroidery, and in the act of
51) a lower rate of duty was imposed on embroidery
on the finer yarns. In accordance with the decision in
se the Treasury Department continued to assess the
mporters, on the other hand, contended for the rate on
otton.
Straus v. *United States*, 7 Ct. Cust. Appls. 414, of 1917,
) carried on appeal to the Court of Customs Appeals
General Appraisers classified as "embroidery cotton"
embroidery machines in the process of making fancy or
lesigns on the face of the fabric, and classified as "yarn"
yarn on bobbins, in which form it is used as the bottom
nbroidery machines to hold the embroidered design in
yarn itself not appearing on the face of the fabric.
dverting to the impetus given to machine embroidery
1909, supra, and reading the provision in paragraph 358
leries * * * and all articles or fabrics embroidered
er by hand or machinery" as indicating a purpose to
and machine products on a parity, held the term
cottons" not restricted to those used in hand embroidery
nly in skeins, and fully sustained the importers' protests
sses of merchandise in issue. This decision was followed
41239, 41620, 41916, 42034, 42068, 42455, 42511, 42525,
In another case (Abstract 42456, of August 9, 1918)
failed to prove that the merchandise was embroidery
ıe collector's classification as "yarn" was affirmed.
yarn in 2-ply strands combined with a slight twist, in
table only for use as embroidery cotton, was held by
Department (T. D. 35873 of 1915) to be dutiable as
otton.
less litigation on spool thread than on yarns for hand-
"spool thread of cotton" comprehends was considered

at length by the Board of General Appraisers in the case under the act of 1894 (G. A. 3609, T. D. 17435). The importation consisted of 2-ply cotton thread roughly wound upon spools, bobbins, or reels, which the board declared to be interchangeable terms. The collector's classification of the merchandise as "spool thread" was sustained.

The phrase "spool thread of cotton" as used in the act of 1897 was interpreted in connection with the added clause "one-half of 1 cent for each one hundred yards or fractional part thereof, if otherwise than on spools or reels." The thread in issue was imported in skeins. Importers offered evidence to prove that the term was applied in commerce only to thread bleached or dyed and wound on spools. This view, however, was not taken by the Board of General Appraisers, which held (G. A. 6952, T. D. 30184 of 1919, following G. A. 4674, T. D. 22080 of 1900) that Congress intended to make the paragraph as enlarged include the merchandise in suit.

In another decision under the act of 1897 (G. A. 4061, T. D. 18748 of 1897) embroidery cotton in skeins was held dutiable at one-half cent for each 100 yards contained in the case, and not at the rate for each skein. This construction was against the Government.

In the act of 1909 the phrase "if in skeins, cones, or tubes, containing less than six hundred yards each, one-half of 1 cent for each one hundred yards or fractional part thereof," was substituted for "if otherwise than on spools or reels, one-half of 1 cent for each one hundred yards or fractional part thereof." This provision was construed by the Treasury Department (T. D. 30175 of 1909) to exclude embroidery cotton in small balls not exceeding 100 yards, which was classified, as before, under the provision imposing the 6-cent rate.

In a review of the legislation and litigation the Board of General Appraisers held unfinished cotton thread in the grey, intended for, and, when completed, suitable for use as, sewing thread, dutiable as "spool thread of cotton," at 15 per cent ad valorem under paragraph 251 of the act of 1913, and not as cotton yarn under paragraph 250. Commercial testimony offered by the Government was declared insufficient to upset the former rulings of the board in the presence of a legislative intent to adopt them. (G. A. 8200, T. D. 37793 of 1918; followed in Abstract 43234 of 1919.)

PREFACE.

This is one of a series of Tariff Information Surveys prepared by the United States Tariff Commission and transmitted to the Committee on Ways and Means. The series covers all of the articles and commodities provided for in the tariff act of October 3, 1913, and others not specifically provided for. It is arranged in the numerical order of paragraphs of that act.

In some cases two or more paragraphs have been combined in one pamphlet. In doing this, industrial relationship of the articles has been followed when possible. In those instances where a paragraph has been treated under a preceding paragraph of the tariff act, reference is made to this fact at the point where the paragraph appears in numerical order. Where one grade of an article is dutiable and another grade of the same article is on the free list, the article is discussed under the dutiable paragraph, which appears first in numerical order in the tariff act. In certain instances articles of close industrial relationship and which occur in separate paragraphs of the tariff act have been combined under one paragraph for convenience of discussion. Reference is made to this fact at the point where the commodities would naturally occur in numerical order.

The first pamphlet in the series is an "Introduction and index," which contains:

1. An introductory chapter discussing the scope of the series and the general method of treatment.
2. An alphabetical index of the articles provided for in the tariff act of 1913, showing the paragraph of the act in which the article is provided for and, if discussed under a different paragraph, the number of such paragraph.
3. A list of the pamphlets in the series, showing the paragraphs and articles included in each pamphlet.

Thus by use of this "Introduction and index," the exact location of the discussion relating to a given article or commodity can be ascertained.

In the preparation of this report the Tariff Commission had the services of Charles F. Yauch and Miss Evelina Kean, of the Commission's staff, and of others.

BROOMS MADE OF BROOM CORN.

BROOMS.

SUMMARY.

Kinds.—According to use, brooms may be classified as follows: (1) Warehouse brooms, wound or metal cased, (2) parlor brooms, (3) toy or hearth brooms, (4) whisk brooms.

Countries of greatest production.—It is estimated that nine-tenths of the world's production of brooms are made in the United States. Canada and Cuba also have broom factories. Japan finds markets for her rice-straw brooms, but they are inferior to articles made from American broom corn. Italy specializes in a soft broom for polished floors made of the native piuma grass. Straw brooms are little used in European countries.

Substitutes.—Vacuum cleaners, carpet sweepers, and patented mops are some of the inventions which, in a measure, replace brooms. None can be put to such a variety of uses as the broom.

Materials.—The ordinary broom is composed of two parts, the handle and the broom or brush. The handles are made by manufacturers of woodenware in States that have abundant supplies of light woods. Broom corn is generally used for the brush. The straw is the seed-bearing portion of a species of sorghum. This is a valuable crop in dry regions and is extensively cultivated throughout the Middle West. Brooms for heavy sweepings are made of bamboo and rattan. Rice straw, hickory splits, Spanish rush, palmetto fiber, and African bass are among the other materials used for this purpose. Articles such as wire, nails, tacks, tin locks, twine, and iron bands are also necessary in broom making.

Process of manufacture.—The operations are so simple that most of the work can be done by hand, but numerous inventions have reduced it almost entirely to a machine process. The corn is prepared for the broom by sorting, sizing, and bleaching, frequently followed by dyeing. The actual broom making consists in winding the corn onto the handle with wire, stitching with several rows of twine, and final trimming or clipping. After a special drying process the brooms are labeled and packed for shipment.

Labor.—It is not difficult to acquire skill in broom manufacture. It is an industry frequently adopted by asylums and penal institutions and is an excellent trade for the blind.

Manufacturing centers.—The manufacture of brooms is not restricted to any one area. The towns of central New York, especially Amsterdam, which has an annual output of over a million dollars, lead in the production of brooms.

Imports.—As broom manufacture is so essentially an American industry, there is practically no foreign competition. The greatest value ever imported was $13,524 in 1918, which, compared to the domestic production of over $14,000,000, is insignificant.

Exports.—The exports are greatly in excess of the imports, yet are small compared to the total output. They amount to some-

thing over $100,000 annually, the largest amount having been $292,729 in 1919, calendar year.

Effects of the war.—Following the general trend, prices on materials for broom manufacture have gone steadily upward. The increase in broom-corn values from about $80 a ton to between $300 and $400 has been the most sensational. The price of brooms has advanced proportionately.

Tariff considerations.—Foreign competition has never seriously troubled domestic broom manufacturers. They are apparently not greatly concerned over the tariff. By the tariff act of 1913 the duty on brooms was reduced from 40 per cent to 15 per cent ad valorem, and broom handles and broom corn were placed on the free list.

Brooms—Summary table.

Year.	Domestic production.	Imports for consumption.	Domestic exports.	Ratio to production.		Value (imports for consumption).	Amount of duty.	Actual or equivalent ad valorem rate.
				Imports.	Exports.			
				Per cent.	*Per cent.*			
1910	[1] $14,431,593	$4,140		0.03		$4,140	$1,656.00	40.00

General Information.

1913 TARIFF PARAGRAPH.

336. Brooms made of broom corn, straw, wooden fiber, or twigs, 15 per centum ad valorem; * * *

KINDS.

It is difficult to enumerate the various classifications of brooms because of the great number of inventions and constructions for special purposes. The most comprehensive classes are: (1) Warehouse brooms, (2) parlor brooms (3) toy or hearth brooms and (4) whisk brooms. The first class comprises heavy brooms used by railroads, oil mills, factories, and warehouses, and may differ in material or construction according to the specific need. To add greater strength brooms for the industrial trade are often made in a metal band 2 inches wide and encircled by another band seven-eighths of an inch wide to reinforce the twine stitching. One example of a special broom is that used by railroads for sweeping frogs and switches. The brush part, usually of stiff material such as reed or rattan, is made thin enough to be inserted in the narrow cracks between the rails.

Light household or parlor brooms are smaller and more attractively finished than warehouse brooms. They come in many sizes and with handles of different lengths for ordinary sweeping or for cobwebbing,

but in the main the method of manufacture in every case is identical. With some improvement in workmanship it is the same as 100 years ago; a bunch of straw is bound to a wooden handle with wire and secured in position by stitching. Toy or hearth brooms are simply diminutive parlor brooms convenient for children or for cleaning old-fashioned brick hearths.

Whisk brooms have short handles to allow a free brisk movement in cleaning clothes or furniture. As they are often an accessory to a dressing table, the handles may be elaborate and costly, of gold, silver, or ivory, or if of less expensive material, ornamented with velvet or nickel.

HISTORY OF THE INDUSTRY.

Because of the simple construction of the broom and its necessity as a household article, the custom of home manufacture was long retained. The broom corn was easily raised and the process of tying the brush to a handle required little dexterity, though the result may have been exceedingly crude. Some Quakers in the town of Hadley, Mass., are said to have been the first to make brooms as a commercial enterprise. Later they moved to Amsterdam, N. Y. A hand factory was started at Fort Hunter, N. Y., in 1857. Two years later the partners in the firm separated and independently opened the first two power broom factories in the world. Various inventions and improvements of machinery have made broom manufacture almost entirely a mechanical process and transformed it from a home into a factory industry.

COUNTRIES OF LARGEST PRODUCTION.

Broom manufacture is primarily an American industry. Straw brooms are little used in European countries. Broom making is not, as in America, a factory industry. The straw broom, known in every home in the United States, seems to be the product of the Western Hemisphere, a fact due to usage and custom rather than to geographic conditions governing the distribution of materials. Establishments similar to those in the United States are prospering in Canada and Cuba; indeed, about the only competition feared by American manufacturers is from the Canadian output. Broom making is a home industry in China and Japan. The Japanese manufacture some for export, but the inferior quality of their brooms made from rice straw, which lacks the durability of American broom corn, eliminates them as serious competitors.

In Italy a compact but soft broom, effective for sweeping highly-polished floors, is made of several bunches of piuma grass, a product of Lombardy. The bunches of fiber are usually secured by a vegetable binder such as raffia.[1]

SUBSTITUTES.

Many inventions excel in some line of cleaning, but none have the universal adaptability of the old-fashioned broom. The vacuum cleaner is a remarkable labor-saving device, but its initial cost places it outside the range of possibility for the average housewife. Carpet sweepers serve their purpose but, as their name implies, are limited

[1] Daily Consular and Trade Reports, Jan. 6, 1914, p. 64.

in their functions. For hardwood floors, mops or hair brushes are usually preferred to a corn broom, as they more easily remove the dust from the polished surface and with less danger of scratching.

MATERIALS.

The ordinary broom is composed of two parts, the handle and the broom or brush. Beech, birch, maple, fir, ash, gum, and other light woods are used for the handle which is simply a turned stick sandpapered, stained, varnished, or otherwise finished to suit the trade.

Michigan, Wisconsin, New York, Pennsylvania, and Maine supply most of the wood used in the manufacture of handles. Redwood, found along the Pacific coast, is used by manufacturers in the West. The broom manufacturer buys the handles ready for the broom. They are made by entirely different concerns, usually interested in a variety of woodenware products. Some of the largest companies are located in Michigan and Wisconsin. Bamboo handles are imported from Japan and China and lacquered handles, claimed to have a superior finish to the American article, are also sent by the Japanese to this country.

For the brush portion of the broom the most universally used material is broom corn. The straw is obtained from the panicle of the plant, which is a species of sorghum. The panicle grows at the end of a stalk 10 to 15 feet high in the standard broom corn and 4 to 6 feet high in the dwarf variety. Some time before the harvesting the panicle is "tabled" or bent to prevent it from growing crooked because of the weight of the maturing seed. While still green the heads with 6 inches of stalk are cut off, cleaned of the seed by hand or machine, and spread in the shade to dry, as the sun injures the color and quality. It is a profitable crop, adapted to dry regions. About 1,000 to 1,200 pounds of dry brush are obtained from 1 acre, and two crops may be gathered in one year. Oklahoma, Illinois, Kansas, and Texas, in the order named, lead in broom corn production. It is extensively raised in many other States, including California, Colorado, New Mexico, Nebraska, Missouri, Indiana, and Tennessee. Illinois corn is said to be the best, although that from the Rio Grande Valley in Texas is of excellent quality.

Broom corn brings the best price when the color is bright green, for which it must be cut in the bloom stage or about 80 days after planting. Discoloration from rain, or being overripe, will often cause a reduction of 50 per cent in the price.

In times of scarcity broom corn is imported from Italy, Austria-Hungary, and Argentina, but the grade is considered inferior to that of the American product.

Warehouse brooms are put to such hard usage that the corn is generally supplemented by split bamboo or rattan as "fillers" to give additional stiffness. For extremely heavy sweepings, all-rattan and all-bamboo brooms are made. Split bamboo or split cane and round rattan are used for snow and switch brooms for railroads.

African bass fiber is the most satisfactory material for packing-house brooms, as it is not affected by hot or cold water and will outwear several of the ordinary corn brooms.

Brooms made in China and Japan are generally of rice straw, but this material is not used extensively in the United States.

The rattan and bamboo, the African bass, bassine, and kittool are imported. Other domestic materials, besides broom corn, from

which brooms are sometimes made, are Spanish rush and palmetto fiber from Florida, and hickory splits from Alabama.

Spanish rush is a wild grass which, since the rise in price of broom corn, has been made use of for the centers, and in some cases for the outside, of cheap brooms. Its wearing qualities can not compare to broom corn, and its substitution should be regarded as fraudulent unless the article is properly labeled.

Wire, nails, tacks, staples, and strips of tin known as tin locks are used to secure the brush to the handle. Twine and iron bands hold the straw in position. These materials are all domestic, except the twine, which is made of imported flax.

The finishings comprise velvet, labels, stains, dyes, and, for whisks, nickel caps. Of these, the only imported article is dye, which, before the war, was obtained from Germany. Manufacturers use cheesecloth, paper, cartons, or wooden cases, or sometimes several of these articles for packing. These may all be obtained in the United States. Brimstone, or sulphur, used for bleaching the corn is also a domestic product.

PROCESSES OF MANUFACTURE.

The manufacture of a broom involves 14 or 15 distinct operations. The broom corn is received at the factory in bales weighing about 300 pounds each. The brush must be sorted according to length. This operation, called sizing, is done by a machine which also cuts off surplus stock. Removing seeds, which may still remain after thrashing, is accomplished by running the brush through the two rollers of the scraping machine fitted with pins or wires. Handwork is necessary for the next operation, sorting to grade and color, but the hurl cutting, ripping, and shaking are done by machinery. As a final preparation for the broom, the corn is bleached with brimstone, or, if necessary, dyed with anilin dyes. For the ordinary broom of the wound style, the brush is secured to the handle by wrappings of wire held in place with nails, and finished with either a velvet strip or a tin broom lock, or both. This is partly done by hand and partly by the winding machine. In this stage of its manufacture the broom is conical, but in the power-sewing machine it is shaped in a vise and stitched with three to six rows of twine. Some seed may still be left in the brush and these are disposed of by a final scraping. The last operation consists in clipping the end of the broom to make it even, after which it is sent to a specially prepared room where the surplus moisture is removed. The finished brooms are bunched in dozens, labeled, and packed for shipment.

LABOR.

In the larger factories the processes are almost entirely automatic. Machinery, however, is not essential for successful broom manufacture. As all the work can easily be done by hand or with the use of simple machinery, it is an industry peculiarly suitable for small establishments, for penitentiaries, and for other State institutions. Because of the ease and safety with which even the power machines may be operated the broom-making trade can readily be acquired by the blind. Most State institutions and vocational schools for the blind make provisions for instruction in this trade.

MANUFACTURING CENTERS.

The industry is widely distributed over the whole country. The is hardly a city without a broom factory, but few are of any si The greatest output of any one establishment does not amount more than a few hundred thousand dollars a year. Amsterda N. Y., has probably a larger production than any other city. cording to Brooms, Brushes, and Handles, for December, 1 7,870,000 brooms, valued at $1,750,000, were manufactured ther one year. The total production for the United States for 1914 over $14,000,000.

Although the industry is not seasonal to the extent that ot are, there is more activity in the spring because of the deman brooms for the spring cleaning.

IMPORTS—REVENUE.

Imports have never been large enough to be a source of anno to the domestic manufacturer, nor a source of revenue to the Go ment. The average imports for consumption for the eight 1910–1917, has been about $4,000. Statistics for imports by tries have not been shown since 1914, but prior to that Japa the principal country of origin, and it is reasonable to suppos she still is. The imports for 1917 were $9,023, about twice the age for the period considered. Imports were highest in 1920, they amounted to $21,871.

EXPORTS.

In 1913 domestic exports of brooms were, for the first tim included with brushes. Exports amounted to $183,643 in 191 did not again equal that figure until 1919, calendar year, when amounted to $292,729. The export trade is principally with Ca Ireland, and countries of the Americas. Ireland is first in the sumption of American brooms.

EFFECT OF THE WAR.

The broom industry, like every other, has experienced adv in the cost of material and labor during and since the war. The of brooms has soared correspondingly.

[1] Census figures for cities are shown by industries for cities of over 50,000 inhabitants. Amsterdam, N. Y., a great broom center, is therefore not shown by industries in census reports. Brooms, Brushes, and Handles, December, 1915, gives the value of brooms produced in Amsterdam, N. Y., as $1,750,000.

[2] Six months ending June 30, 1921.

COURT AND TREASURY DECISIONS.

Bundles of bamboo strips about one-eighth of an inch wide and 6½ inches long, tightly tied together at one end with similar bamboo or rattan strips, and used to clean sinks, were held by the Board of General Appraisers dutiable as brooms under paragraph 336 of the act of 1913. (Abstract 38158, T. D. 35696.) Abstract 38158 was followed by the board upon an unsatisfactory record, without approving the action of the collector. (Abstract 40232.) Customs officers were instructed by the Treasury Department to continue to classify such articles as brushes, under paragraph 336, pending a judicial determination of the question.

Abstract 38158 was again followed by the board in Abstract 41549. Owing to the unsatisfactory nature of the record in Abstract 41549 customs officers were informed that a new case would be made, and instructed still to classify the merchandise as brushes under paragraph 336 of the act of 1913. (T. D. 37502.)

An importation described as bamboo pot scrubs, classified as brushes under paragraph 336 of the act of 1913, were held dutiable as brooms under the same paragraph. The Board of General Appraisers, referring to the instructions of the Treasury Department in T. D. 37502, supra, said:

> There being no change in the law, and the facts being the same, the unreversed decisions of this board, which is the only customs court of original jurisdiction, are as binding and conclusive as a final determination of the question presented as could be found in the decision of any other court to which causes may be carried. The customs officers may not make cases, as suggested by the department letter. The customs officers examine the goods and classify them according to law and fact. If they are found identical in character with goods already passed upon, on appeal to this court the last unreversed decision of this court on the subject is the law of the case. If a different state of facts is found to exist, the collector may act according to the facts, and, if a protest is entered, on the trial of the case the testimony may or may not justify his action.

Patent rotary wire brushes with four rows of phosphor bronze bristles used in connection with an apparatus for cleaning the Fourdrinier wire of a paper-making machine, are dutiable as brushes within the meaning of that word as used in this paragraph. (Abstract 37023, T. D. 34984, of 1914.) *Jewelry brushes*, consisting of brass scratch brushes used for polishing gold and jewelry, are dutiable as brushes under this paragraph rather than as wire under paragraph 114. (Abstract 36472, T. D. 34763, of 1914.) *Toothbrushes and bamboo baskets* containing cardboard trays in which the toothbrushes are packed, the baskets used upon the counters of retailers to display the toothbrushes, were held dutiable under paragraph 175 and this paragraph, the baskets being treated as unusual coverings. (Abstract 43037, of 1919, following G. A. 7592, T. D. 34676, of 1914, relative to show cases filled with pipes and to be subsequently refilled.) *Boot wipers*, consisting of an iron stand and two brushes, were held dutiable as entireties at the rate applicable to the component acticle of chief value. (G. A. 7802, T. D. 35846, of 1915.) A *rubber mat*, oval in shape, in which are set by means of adhesive material bristles of the length and character of the bristles in a hairbrush, capable of use as a hairbrush, was held dutiable under the provision for brushes under this paragraph either directly or by similitude. Articles in form, shape, and design similar to if not identical with the ordinary hairbrush, is in effect a hairbrush minus the handle. (Abstract 40862, of 1917.)

Merchandise invoiced as "*reversible cotton bath pads*" and "*cotton bath straps*," and composed of cotton and loffah, classified as brushes under this paragraph, was found not to respond to the definition heretofore given of brushes in the construction of the paragraph, but as the component material of chief value was not shown the protest was overruled. (Abstract 41242, of 1917.) A *round wooden stick* about 18 inches long, at one end of which is a whisk effect produced by small shavings of the stick turned down and bound together, were found not to be capable of use as brooms or brushes, but held dutiable as manufactures of wood under paragraph 215 of the act of 1909. (United States *v.* Swedish Produce Co., 4 Ct. Cust. Appls., 330, of 1913.) *Clarinet*

cleaners consisting of twisted pieces of wire and having yarns or threads run nearly at right angles with the wire were held dutiable as brushes under paragraph 423 of that act. (T. D. 32512, of 1912.) *Miniature feather dusters* were held to fall within the terms of paragraph 423 of the act of 1909 as "feather dusters of all kinds" and not dutiable as toys. (United States *v.* Scheuer, 4 Ct. Cust. Appls., 37, of 1913.)

Twigs, probably of willow, closely bound together in bundles securely fastened at one end and of substantial strength and apparent durability, were found to be brushes known as whisk brooms, and were held dutiable under paragraph 423 of the act of 1909. (United States *v.* Swedish Produce Co., 4 Ct. Cust. Appls., 331, of 1913.) Brooms of willow twigs, bunched together and tied at the heavy ends with wooden thongs, about 1 foot in length and suitable for various purposes, said to be used in Sweden and among Swedish people for beating eggs and gravy and for other culinary purposes, were held dutiable under the first clause of paragraph 336 as brooms rather than under the latter part of the paragraph as brushes. (Abstract 40781, of 1917.) So-called bamboo sink brooms or brushes were held to be dutiable as brooms under paragraph 336. (Abstract 41549, of 1917.)

BROOM CORN.

General Information.

1913 TARIFF PARAGRAPH.

434. Broom corn. Free.

DESCRIPTION AND USES.

Broom corn belongs to the sorghum group of plants. Two kinds, "standard" and "dwarf" are commonly grown. The dwarf is produced in the semiarid regions of the Southwest, the standard in the more humid sections of Illinois, Kansas, Oklahoma, and Texas. The standard bush is 18 to 30 inches long, used largely in carpet brooms; the dwarf makes a brush 1 or 2 feet long, such as the whisk and other small brooms. Special equipment in the form of drying sheds, thrashers, and balers is required in broom-corn production.

PRODUCTION.

Production of broom corn is from 52,000 to 57,000 tons, with normal average value of $5,000,000. In 1917 the farm value of 57,40[illegible] tons was $16,800,000. The principal producing States are Oklahom[illegible] and Texas. The product for 1920 has been estimated at 33,000 tons valued at $4,263,000.[1]

IMPORTS.

Imports before the war came principally from Austria-Hungary and Italy. In 1910 they amounted to $934,000, of which $373,04[illegible] originated in Austria-Hungary and $290,784 in Italy. Since 191[illegible] imports have varied greatly, and they have in only one year, 191[illegible] amounted to approximately one-half of the 1910 figures.

[1] Monthly Crop Report, Dec., 1920, Dept. of Agr.

EXPORTS.

The export trade in broom corn is principally with Canada and Cuba. In the year 1918, when exports amounted to 3,992 tons, valued at $1,018,111, and Cuba 886 tons, valued at $253,356. Imports were lowest in 1914, in which year 2,959 tons, valued at $327,426, were exported.

TARIFF HISTORY.

The act of 1890 imposed a duty of $8 per ton, and that of 1909 a duty of $3 per ton. Under the acts of 1894, 1897, and 1913 no duty was imposed.

PREFACE.

This is one of a series of Tariff Information Surveys prepared by the United States Tariff Commission and transmitted to the Committee on Ways and Means. The series covers all of the articles and commodities provided for in the tariff act of October 3, 1913, and others not specifically provided for. It is arranged in the numerical order of paragraphs of that act.

In some cases two or more paragraphs have been combined in one pamphlet. In doing this, industrial relationship of the articles has been followed when possible. In those instances where a paragraph has been treated under a preceding paragraph of the tariff act, reference is made to this fact at the point where the paragraph appears in numerical order. Where one grade of an article is dutiable and another grade of the same article is on the free list, the article is discussed under the dutiable paragraph, which appears first in numerical order in the tariff act. In certain instances articles of close industrial relationship and which occur in separate paragraphs of the tariff act have been combined under one paragraph for convenience of discussion. Reference is made to this fact at the point where the commodities would naturally occur in numerical order.

The first pamphlet in the series is an "Introduction and Index," which contains:

1. An introductory chapter discussing the scope of the series and the general method of treatment.
2. An alphabetical index of the articles provided for in the tariff act of 1913, showing the paragraph of the act in which the article is provided for and, if discussed under a different paragraph, the number of such paragraph.
3. A list of the pamphlets in the series, showing the paragraphs and articles included in each pamphlet.

Thus by use of this "Introduction and index," the exact location of the discussion relating to a given article or commodity can be ascertained.

In the preparation of this report the Tariff Commission had the services of Percy W. Bidwell, of the Commission's staff, and of others.

STRAW HATS.

RAMIE HAT BRAIDS.

GENERAL INFORMATION.

1913 tariff paragraph.—334. Ramie hat braids, 40 per cent ad valorem; manufactures of ramie hat braids, 50 per cent ad valorem.

Description and uses.—Ramie braid, used for making hats, resembles silk braid, and may be made by hand or by machinery, as other hat braid.

Production.—The production of ramie hat braid is not very extensive, importers claiming that the demand for it in this country has ceased entirely. Switzerland is the chief producer, but some is made in Italy, Germany, and France. The raw material from which ramie hat braid is made comes almost wholly from China and Formosa.

Imports.—Imports of ramie hat braids or manufactures thereof are not shown by countries. Imports of hat braids amounted to $3,018 in 1914 and $150 in 1920. In 1918 they amounted to $6,475, the highest. Imports of manufactures of ramie hat braids amounted to $4,033 in 1917. In other years they have amounted to less than $1,000 with the exception of 1916, when they amounted to $1,701.

Tariff history.—The act of 1913 was the first to provide specifically for ramie hat braids. In previous tariff acts ramie hat braids were dutiable under the paragraph relating to braids composed wholly or in chief value of cotton, flax, or other vegetable fiber and not elsewhere specially provided for. Under the act of 1894 ramie braids were dutiable at 45 per cent ad valorem, under the acts of 1897 and 1909 at 60 per cent ad valorem, and under the act of 1913 at 40 per cent ad valorem.

STRAW HATS AND STRAW-HAT MATERIALS.

SUMMARY.

Kinds of hats produced in the United States.—The principal business of straw-hat factories in the United States is the production of sewn-braid hats, i. e., hats made by sewing plaits or braids, of straw or other vegetable fibers, into the shape of hat bodies. Woven-body hats, rough hoods or forms woven of straw or other vegetable fibers, are also finished and trimmed in American factories. The manufacture of sewn-braid hats constitutes the bulk of the business in every large hat factory; the trimming and finishing of the woven-hat bodies is important but subsidiary.

Materials.—The principal materials used in the manufacture of sewn-braid hats are braids and plaits of straw, chip (wood shavings), and hemp. All braids are imported, chiefly from Japan (60 per cent), China, and Italy. Imports of braids for 1920 were $9,137,696, and the average for the years 1914–1920 was $7,502,457. Woven-hat bodies come from Colombia, Ecuador, and Peru, the Philippine Islands (Bangkoks and Buntals), Porto Rico, Japan (paper Panamas), Italy (Leghorns), China, and the East India Islands. The imports of hat bodies not blocked or trimmed were valued at $2,457,264 in 1920; the average for 1914–1920 was $3,772,783. The braiding of straw plait and the weaving of hat bodies are hand occupations performed by cheap labor, largely that of women and children, in the homes of the workers in foreign countries. With the exception of a small quantity of fancy braids of artificial silk and ramie fiber, neither braids nor hat bodies are at present produced in this country. Accessory materials, such as chemicals for bleaching and dyeing, cotton thread, glue, silk hatbands, leather sweatbands, and miscellaneous trimmings were imported (practically the entire supply) before the war, but all are now produced in this country.

Manufacturing processes.—The principal processes involved in the manufacture of men's sewn-braid hats are—(1) Bleaching the braid. (2) Sewing the braid. (3) Sizing or stiffening the hat bodies. (4) A sulphur bath. (5) Pressing. (6) Finishing. (7) Trimming. Women's sewn-braid hats are made in the same way, except that the braid used is generally dyed, instead of being bleached, and the women's hats are varnished after pressing. The trimming of women's hats is usually done in retail stores, although many thousand dozens of hats are sent out from the factories "ready to wear." Woven-hat bodies for both men's and women's wear are imported in the rough, and bleached or dyed, pressed and trimmed in American factories. Sewing, the most important and expensive operation in-

volved in the manufacture of sewn-braid hats, does not enter into finishing and trimming of woven-hat bodies. Hence the labor cost is less, but since bodies are more expensive than braids the material cost is considerably higher.

Production in the United States.—In 1914 straw hats to the value of $27,918,553 were produced in 149 factories, chiefly in the States of New York, Maryland, Massachusetts, and Pennsylvania. With the exception of a few large factories in small towns in Massachusetts, the industry is urban, being concentrated in New York, Baltimore, and Philadelphia. Of the total production, women's hats amount to approximately $15,500,000, or 55 per cent, and men's, boys' and children's hats to $12,500,000, or 45 per cent. Men's and women's hats are, with negligible exceptions, invariably produced in separate establishments. The materials used and the processes involved are similar, and although the styles of men's hats show more uniformity, a surprising amount of standardization has been attained in the output of large factories producing women's hats. The reason for the separation of the production of men's and women's hats into two distinct branches of the industry seems to lie in the difference in the character of the demand for the products and in the consequent difference in marketing problems. Production in both branches is seasonal. In the case of women's straw hats, the "busy" season lasts from November 1 to June 1. Velvets and felt hats are made in the summer and early fall months, but with reduced labor force.

Wage earners.—The average number of laborers employed in the straw-hat industry in 1914 was 9,483, comprising about 40 per cent men and 60 per cent women. The women who are employed in sewing the braid should be regarded as skilled laborers. A period of apprenticeship or training of one or two seasons is necessary to acquire proficiency. Added skill, resulting in considerably increased wages, is gained for several years. Operatives, who might be called partly skilled, are the men engaged in blocking, pressing and finishing hats.

Competition.—Production of women's hats in this country is on a larger scale, turning out a more standardized product, than in foreign countries. In foreign countries, straw-hat factories are principally engaged in the production of men's hats. Only women of the upper classes wear hats regularly in many foreign countries, and consequently the demand is not large enough to warrant standardized production on a large scale. The rapidity of style changes and the necessity of quick deliveries make foreign competition in the American markets impossible. A few French hats are imported every year, but these are mostly used as models.

The imports of trimmed hats are almost entirely finished hats for men's wear. In 1914, the year of the last census of manufactures, imports of finished hats amounted to $903,179, the maximum figure. In the same year the American production of men's straw hats was $12,500,000, the ratio of imports to production being 7.2 per cent. A more accurate idea of the extent of foreign competition is obtained by comparing the production of men's hats in 1914 with the average annual imports for the years 1914–1917:

Average annual imports 1914–1917	$468,025
Production of men's hats in United States in 1914	$12,500,000
Ratio of imports to production.....per cent..	3.7

Men's straw hats are imported chiefly from England and Italy. In both countries some of the processes of production are carried on in the homes of the workers. Machinery for sewing and pressing hats is used abroad to practically the same extent as in this country, but it is not so generally operated by power. Labor costs and the costs of raw materials, according to the best evidences obtainable, are lower in foreign countries. Added elements in the cost of materials for American hats are the tariff duties imposed by our law.

The war has decreased foreign competition. Foreign costs of production have risen more rapidly than domestic costs, and in addition the expenses of packing and transportation have increased. Consequently, the prices of foreign hats in the American market have shown greater advances than the prices of domestic hats. The importations from England have decreased from $374,500 in 1914 to $157,700 in 1917.

Exports.—Straw hats are exported principally to Canada, and in smaller quantities to Mexico, Cuba, and South American countries. The volume of export trade can not be accurately estimated. Men's straw hats until 1917–18 were included in the exports of manufactures of straw and palm leaf, and women's hats in artificial flowers and millinery. The value of the exports in both categories was $2,564,142 in 1917. In the same year the Canadian imports of straw hats from the United States were $1,545,583. From these statistics it seems probable that the exports of men's and women's straw hats to all countries from the United States in 1917 were about $2,000,000, approximately 7 per cent of the value of all straw hats produced in the United States in 1914.

The effect of the war has been an increase in the opportunities for the sale of American straw hats in Canada, South America, and Australia, owing to the difficulties which Italian and English manufacturers have had in securing supplies of braid and in shipping their products to export markets. Transportation difficulties have prevented the American manufacturers from taking full advantage of the increased export opportunities.

Straw hats [1]*—Summary table.*

1918		3,023,512	631,522	3,023,512	631,524
1918 [3]		[4] 2,910,040	[5] 597,184	[4] 2,910,040	600,082
1919 [3]		[4] 4,014,708	[5] 739,785	[4] 4,014,708	882,722
1920 [3]		6,157,390	[5] 1,212,025	6,157,390	1,491,186

[1] Including all hats imported, both blocked or trimmed and not blocked or trimmed.

[2] Manuactures of straw and palm leaf, including men's straw hats and also dyed straw braid, but not women's hats, which up to 1916 were not separately stated. In 1916 women's hats were classified under "Artificial flowers and millinery."

[3] Calendar year.

[4] Does not include paper hats, imitation Panamas, or manufactures of ramie hat braids.

[5] Exports of men's hats, other than felt, only.

Ratio of imports to production not computed, because not directly comparable. The figures for imports given in this table include the value of hats, not blocked or trimmed, which are used as materials in the production of the domestic hats. Ratio of exports to production not computed, because not directly comparable. Equivalent ad valorem rate not computed. Because hats, blocked or trimmed, are dutiable at a different rate from hats not blocked or trimmed.

Straw hats, not trimmed [1]*—Summary table.*

Year.	Imports for consumption.	Value (imports for consumption.)	Amount of duty.	Equivalent ad valorem rate.[4]
1910	$2,517,866	$2,517,866	$834,869	33.19
1911	2,598,066	2,598,066	861,879	33.17
1912	3,948,966	3,948,966	1,264,467	32.02
1913	4,146,925	4,146,925	1,347,309	32.49
1914	4,577,021	4,577,021	1,128,556	24.66
1915	4,266,902	4,266,902	1,001,833	23.48
1916	4,429,664	4,429,664	1,009,231	23.11
1917	4,530,092	4,530,092	1,007,210	22.23
1918	2,789,547	2,789,547	539,066	19.32
1918 [2]	[3] 2,711,943	2,711,943	529,948	19.54
1919 [2]	[3] 3,844,888	3,844,888	816,426	21.23
1920 [2]	[3] 4,770,858	4,770,858	997,286	20.90

[1] By the act of Oct. 3, 1913, the classification was changed from hats, not trimmed, to hats, not blocked or trimmed.
[2] Calendar year.
[3] Does not include paper hats, imitation Panamas.
[4] The act of Oct. 3, 1913, lowered the rate from 35 to 25 per cent ad valorem. The divergences shown in the table are due to the inclusion of Philippine and Cuban imports, dutiable at rates less than imports under the general tariff.

[1] Changed to hats, blocked or trimmed, by the act of Oct. 3, 1913.
[2] Including $1,271,973 reported by concerns in allied industries.
[3] Including $2,474,553 reported by concerns in allied industries.
[4] Calendar year.
[5] Does not include paper hats, imitation Panamas.
[6] The act of Oct. 3, 1913, lowered the rate from 50 per cent to 40 per cent ad valorem. The divergences shown in this table are due to the inclusion of Philippine and Cuban goods, dutiable at rates less than imports under the general tariff.

General Information.

1913 TARIFF PARAGRAPH.

335. Braids, plaits, laces, and willow sheets of squares, composed wholly or in chief value of straw, chip, grass, palm leaf, willow, osier, rattan, real horsehair, cuba bark, or manila hemp, suitable for making or ornamenting hats, bonnets, or hoods, not bleached dyed, colored, or stained, 15 per cent ad valorem; if bleached, dyed, colored, or stained, 20 per cent ad valorem; hats, bonnets, and hoods, composed wholly or in chief of straw, chip, grass, palm leaf, willow, osier, rattan, cuba bark, or manila hemp, whether wholly or partly manufactured, but not blocked or trimmed, 25 per cent ad valorem; if blocked or trimmed, 25 per cent ad valorem; if blocked or trimmed and in chief value of such materials, 40 per cent ad valorem. But the terms "grass" and "straw" shall be understood to mean these substances in their natural form and structure, and not the separated fiber thereof.

I. DESCRIPTION.

Straw hats may be divided into two general classes according to the processes of manufacture, viz: (1) sewn-braid hats, (2) woven-body hats. In producing sewn-braid hats, straw, grass, or other similar material is first plaited into braids; then these braids are sewn together in spiral fashion along their overlapping edges into the rough shape of a hat body. In making woven-body hats, on the other hand, the straw or other material is not braided, but is woven by hand into rough hat bodies, or hoods, as they are called. The processes of blocking and trimming of both sorts of hats are essentially similar, as will appear in the subsequent discussion of the processes of manufacture.

In reply to the question, "What are the comparative advantages of sewn-braid and woven-body hats?" representative manufacturers have given the following answers:

Woven bodies are stronger and can be cleaned and bleached easier after the hat is made up. They are also cheaper.

This we believe is entirely a matter of individual taste, style, or price. The better woven hats are higher in price than braid or sewn hats.

Sewn hats are as a rule more durable. The purchase of either kind is subject to individual taste and the fashions.

Sewn-braid hats require gluing and will not stand rain. Woven-body hats are more serviceable in all kinds of weather, fit snugly, shed rain, etc.

The sewn hat seems to have the preference over the woven-body of any description by the women. This may be caused by the fact that we can make much more intricate shapes and better looking hats for no more money.

Most of the braid hats are more durable. Woven-body hats are generally lighter in weight and lend themselves to blocking in fancy shapes, as for instance, Alpine, telescope shapes, etc.

Practically all large manufacturers of either men's or women's hats produce woven body as well as sewn-braid hats, the bulk of the business being almost always found in the production of the former variety. The finishing and trimming of woven bodies is subsidiary, amounting usually to about 20 per cent, although sometimes as high as 40 per cent of the total business done in each factory. Thus the large manufacturers by being prepared to supply either kind of hats, insure themselves against sudden changes of fashion. The "body" business seems to have more flexibility than the manufacture of sewn-braid hats. Rough hoods or bodies can be blocked and finished in a wide variety of shapes. They also required less expenditure of labor and consequently the output can be varied more easily than in the case of sewn-braid hats. Small manufacturers do not generally devote as much attention, proportionally, to the trimming and finishing of woven-hat bodies as do the large firms, because of the larger investment of capital required in purchasing the imported hat bodies in the rough.

There are many kinds of both sewn-braid and woven-body hats, depending (1) on the kind of material of which they are composed, i. e., whether straw, palm, leaf, wooden chip, manila hemp, rush, grass, etc.; (2) on how this material is braided or woven; (3) on the shape which is finally given the hat in the processes of blocking and pressing; and (4) on the kind and quality of trimming used. Men's hats, like other articles of their wearing apparel, show more tendency to standardization than those made for women's wear. Most of the men's hats are made in a few uniform shapes such as (1) the yachting

or "sailor" type, with a flat crown and stiff brim; (2) a similar shape with a higher crown and flexible brim worn by older men; and (3) the Alpine or Fedora style, in which the Panamas are usually seen. Yet the extent of standardization is not nearly so great as appears, for within each class or style of men's hats there are not only 11 different sizes, but there are also a great number of varieties, depending on the height of the crown, the width of the brim, the kind of straw braid or woven body used, and the quality and style of trimming used. The number of possible combinations of those variations is so large that some large manufacturers are prepared to take orders for as many as 2,000 different kinds of men's hats.

Great variety is to be expected in women's hats, but even here an approach to standardization in shapes is discoverable. Each of the large manufacturers offers at the beginning of the season a few shapes as samples and then produces these hats on orders. Popular shapes are produced in hundreds of dozens. All women's hats are of the same size.[1] The variety observed in women's straw hats is largely, therefore, the result of the details of the trimmings which are added in the millinery shops and stores.

II. MATERIALS USED AND PRINCIPAL SOURCES OF SUPPLY.

A. SEWN-BRAID HATS.

The principal materials used in the manufacture of straw sewn-braid hats are braids or plaits of straw, chip, grass, and other vegetable fibers. Accessory materials are chemicals for bleaching and dyeing, cotton thread used in sewing the braid, glue or gelatin for sizing, and miscellaneous materials for trimming.

1. *Braids for men's hats.*—The straw braids most used at present for men's hats are plaited in Japan and in China. From Japan come large quantities of braid known as sennit, which is almost exclusively used in the production of stiff-brimmed sailors or yachting hats. The sennit braid is made of wheat straw, harvested before the grain is ripe. The straw, which grows about 30 inches high, is divided into three cuttings of 8 to 10 inches in length. Of these the first and second, counting from the top, make the best quality of braid. The short lengths of straw are plaited together and spliced at the ends, making a continuous piece. The "piece," the unit of measurement used by importers as well as by manufacturers, is generally estimated at 60 yards in length, although some braid is sold in pieces of 120 yards.

Sennit braids may be of any width from 6 to 22 millimeters; widths of 11 to 18 millimeters are at present most in demand. The details of appearance and finish of braid depend upon the process of plaiting, i. e., whether whole or split is used, and upon the number of strands or "ends" of which the braid is composed (e. g. whether 3, 5, or 7 ends).

Chinese braids are narrower than the Japanese, varying from 5 to 11 millimeters in width. They lack the clear, pale yellow color of the Japanese straw, and since the business of plaiting braid is not systematically organized in China, the quality of workmanship is more apt to be inferior. The Chinese braid principally used by

[1] That is, all hats of any particular shape.

American manufacturers of men's hats is the 7-end split, composed, as the name suggests, of seven strands of split straw. Other braids are the shansi, also called shingkee or Mashenpoo, a 7-end braid of whole straw, and Laichow mottled, also known as patent Milan. The latter is of low grade both in color and in workmanship. Shingkee and patent Milan are used in the cheapest variety of sewn-braid hats, "coarse" and "coarse fine," for men and boys.

2. *Braids for women's hats.*—For women's hats, braids of three materials are principally used; straw, hemp, and chip (i. e. wood shavings). The best straw braid is the Italian Milan, imported in normal years in large quantities. It is manufactured from straw grown in Tuscany. "Generations of Tuscan women have braided straw and seem to do the work mechanically. They are wonderfully deft, never looking at the strands, braiding while talking or walking or while carrying bundles upon their heads. Braid making furnishes an occupation to thousands of women and girls and is a home industry, to be taken up or put down as circumstances require. * * * The work is paid for by the piece, and earnings range from $0.08 to $0.40 per day, the latter amount being for the most expert workers." [1]

The war conditions seem to have unfavorably affected the quality of Italian braids. "With the increased demand and the scarcity of labor, the goods shipped have not always been up to standard. Many of the most skillful braiders, who are always women, left their work for more lucrative work offered by contractors for army supplies; others to work on small farms from which men had been called to the colors. This, together with the pressure put on workers by the 'fattorini,' in order to turn out sufficient work to supply the increased demand, and the fact that numbers of unskilled women and children had to be employed, necessarily affected the quality of the work. Upon the offer of better wages many women returned from Government work, but throughout the season hands were scarce." [2]

Italy also bleached and exported, before the war, considerable quantities of Japanese and Chinese straw braids. Transportation difficulties have decreased this business, but reexports of Swiss braids are still an important item.

Chinese straw braids known as piping and 7-end split are of good quality and are much used in women's hats. From China is imported also a braid known as patent Milan which, as the name implies, is an imitation of the high-grade Italian product. A 2-end straw braid for women's hats is imported from Japan.

Hemp braids have been in recent years a very popular material for women's hats. The bulk of the United States supply has come from Japan, amounting in 1919 to 4,563,000 bundles, worth $837,000. Italy also supplies hemp braid, the raw material for which originates in the Philippine Islands.

The cheapest braid used in women's hats is known as chip. The material used is not straw but wood shavings, although it is sometimes known as rice straw. The method of preparing this material is described by a United States consul in Italy.

---

[1] United States Commerce Reports, Feb. 4, 1916.
[2] Supplement to United States Commerce Reports, Annual Series, May 17, 1916.

"Truciolo" straw is made into braids at Carpi, a town near Modena, in this consular district. These braids are employed for "chip" hats. The material used is not straw at all, although it is sometimes known as "rice straw." Great numbers of white poplar trees are grown in the river Po region in the Province of Reggio Emilia and Ferrara, especially for the manufacture of this "straw." Four or five years after planting the trees are felled. All straight trunks and branches are cut into lengths of 20 to 24 inches, the bark removed, the piece squared and planed. The pieces are then passed through a special machine that cuts them into strands of any desired width and thickness. Three of these strands are used to plait a braid. The braids can be colored or bleached to any desired shade.[1]

A hat of chip braid when lacquered closely resembles the more expensive straw hat, but its wearing quality is much inferior. Chip braid is also imported from Japan in large quantities.

Besides the staple braids described above, small quantities of fancy braids are imported, of materials such as horse hair, artificial silk, and ramie fibers. Fancy braids can not usually be sewn on machines; consequently they are not suitable for the production of standardized hats in large quantities.

3. *Imports of braids.*—The total imports of braids in 1920[3] were valued at $16,340,585. Of this amount Japan supplied braid valued at $6,104,343; China, $8,379,819; Italy, $1,118,779; France, $60,547; and England, $369,766. Japan's importance as a source of braids has increased remarkably since the outbreak of the present war. The United States consul, Kobe, Japan, recently reported:

The manufacture of hats and hat braids was an important industry in this district even before the war, but since supplies from Italy, which was Japan's principal competitor, were cut off, the output here has increased enormously.[2]

The above report is substantiated by an examination of the figures for imports for 1916 and 1917. The value of Japanese braids imported increased from $3,315,000 in 1916 to $6,104,343 in 1920[3]; the imports from Italy decreased from $1,017,000 in 1916 to $672,000 in 1917, but in 1920 were $1,118,779. Considering the statistics over the six-year period, 1912–1917, we get more dependable results. For the three years preceding July 1, 1914, Japan supplied 44 per cent of the braids imported into the United States; in the three years succeeding, the proportion was 60 per cent. The value of imports from China and Italy have increased both absolutely and relatively since 1914, whereas the share of England and France in the trade has shown considerable decrease.

4. *Hat braids not produced in the United States.*—With the exception of a small quantity of fancy braids, none of such material for the manufacture of either men's or women's straw hats is at present produced in the United States. A manufacturer has written on this subject as follows:

A few of the Indians in the vicinity of the Mackinaw Straits, plaited some braid which was called Genuine Mackinaw. The production was never large, and was very uneven and irregular both in quality and widths, so that the handling of the braid was more or less of a problem. Somebody from America or Japan got hold of a piece of this braid and plaited an imitation in Japan, which was regular and very much lower in price, and in a very short while stopped entirely the small production of the Genuine Mackinaw braid.

The plaiting of straw braids was long a household industry of importance in small Massachusetts towns, but has now entirely disappeared.

[3] Calendar year.

B. WOVEN BODY HATS.

The finishing and trimming of woven hat bodies constitutes a part of the business of all large straw-hat factories. Hat bodies are always imported "in the rough," i. e., not blocked or trimmed, and consequently should be regarded as a semimanufactured material. The entire supply of hat bodies is at present brought in from foreign countries, where the weaving is a household industry requiring a high degree of skill. The domestic industry of weaving palm-leaf hats, which, like the plaiting of straw braid, was formerly a household industry in rural sections, has now entirely disappeared. The principal sources of supply are South America, the Philippine Islands, Japan, Italy, and the West Indies. In 1920 of the total imports of hats, not blocked or trimmed, amounted to $3,261,981.[1] Colombia, Ecuador, and Peru supplied $1,372,326; Japan, $34,232; and the Philippine Islands, $583,256. Taking an average of the annual imports since 1915, however, we find Japanese goods more than twice as important as those received from the Philippines. The latter have shown an increase in value of from less than $260,000 in 1915 to over $580,000 in 1920.[1]

1. *Panama hats.*—From Colombia, Ecuador, and Peru we get the hats known as Panamas. The name at present, is misleading, because very few of these hats are produced on the Isthmus. It was attached to the product because Panama was the point of transshipment for all goods from the west coast of South America. Two other names, Toquilla and Jipijapa, are given to the hats. The former refers to the palm tree which supplies the fiber from which the hats are made; and the latter refers to a town in Ecuador, whose inhabitants are largely engaged in weaving the hats.

The production of Panama hats is a household industry carried on by thousands of families in the interior of the three Republics. The "straw" which furnishes the material is taken from the leaves of a palm tree (*Carludovica palmata*) which grows in the tropical and damp zone of Colombia, in the forests of Peru, and on the banks of the Amazon River. The Ecuadorian plants, however, furnish the highest quality of straw, used by producers in both Colombia and Peru. A considerable amount of careful preparation is required before the straw is ready for weaving. The leaves are cut from the trunk of the tree before they open, or just as they ripen, are soaked in hot water, and then bleached by drying in the sun. Weaving, a hand process entirely, is done in the early morning and in the late evening, when the moisture in the air keeps the fiber pliable. The native women and children become the most successful hat weavers, although men are sometimes found with sufficient deftness of fingers to be successful in the art. To weave a hat of fine quality may require from three to six months, working from four to five hours daily. Such hats are sold in foreign retail markets at prices varying from $25 to $100 each. The Panama hats which sell in retail stores in the United States at $5 each are bought in South America at about $24 a dozen. Hats similar to the genuine Panama are imported from Jamaica, Curacao, and other islands in the West Indies.

[1] Calendar year.

2. *Japanese Panamas.*—A cheap imitation of the Panama hat is imported from Japan. The material is paper made from a pulp of vegetable fiber. The paper is cut into fine strips, which are braided by hand. The Japanese hats, called Toyos or Adambas, closely resemble the South American products in appearance, but are heavier and do not stand the weather as well. They sell at a much lower price than the genuine Panamas, consequently the importation has increased rapidly in late years. The Japanese statistics show an exportation of 162,200 dozen of imitation Panama hats to the United States in 1913, 260,000 dozen in 1914, and 200,000 dozen in 1915.[1] In 1916 the value of the exports of these hats to the United States was $2,090,000,[2] by 1918 the value had fallen to $639,209.

3. *Philippine hats.*[4]—The weaving of straw hats is one of the many important household industries in the Philippine Islands. Of the many kinds of hats produced there, the varieties chiefly exported to the United States are: Bamboo hats, sold in this country as Java or Manila hats. They are easily produced and sold at a low price, but are not so durable as other varieties. Exports to the United States in 1916, 256,000, value, $103,200; in 1919, 43,642 with a value of $70,582.

Buri and Arayat hats, made of the fiber of the leaves of the buri palm, are very cheap hats, being worn in this country in the harvest fields and at the seashore. Exports to the United States in 1916, 729,200, value, $34,250; but fell off in 1919 to 45,112 worth $10,830.

Buntal hats, called also Bangkok or East Indian Panamas, are made from the fiber of the leaf stem of the buri palm. They are of a beautiful silky texture, light straw in color, weigh very little, and are durable. "The export demand for buntal hats is greater than the supply, and all that can be obtained from Manila are shipped abroad, mostly to Paris and New York. These hats have long been used in the United States, but direct import has grown to large proportions only since the advent of free trade, the hats having been brought in from Paris previous to that time. Buntal hats are very popular in the United States, and a growing market may be relied upon there." [3] The buntal hats are the most expensive of the Philippine product, retailing in this country from $10 upward. Exports to the United States in 1916, 317,200, value, $440,750; and 350,721 with a valne of $574,849 in 1919.

4. *Leghorn hats.*—The Leghorn hats imported from Italy have long been famous. They are not, strictly speaking, woven-body hats, being constructed of narrow straw braids sewn edge to edge instead of overlapping as in the standard sewn braid hats. Straw, instead of thread, is used in sewing. Chip hats, woven hat bodies made of wood shavings, are also imported from Italy. Since the imports of untrimmed hats are not segregated in the official statistics of importation by countries, it is impossible to give exact figures for the imports of woven hat bodies from Italy. The United States consul at Florence, the chief port of exportation, reported that shipments of unblocked hats from that district had decreased from 162,200 dozen,

[2] Supplement to the United States Commerce Reports, Annual Series No. 55c. Dec. 31, 1917.
[3] Miller, Hugo H. Philippine Hats, Bulletin No. 33 of the Bureau of Education. Manila, 1910, pp 37–38.
[4] Figures for the exports of Philippine hats are taken from the Annual Reports of the Bureau of Customs Department of Finance, Government of the Philippine Islands. 1916, pp. 211–213, and 1919, pp 227–228.

valued at $917,500 in 1916, to 73,500 dozen, valued at $374,400, in 1917.[1]

5. *Other hats.*—From Porto Rico the imports of manufactures of straw and palm leaf, consisting chiefly of woven-body hats, steadily increased from 1910, to the year 1917 with a total of $569,400. Since that there has been a large decrease, in 1920 (calendar year) the total value was $131,952. Concerning the industry in Porto Rico, a special agent of the Department of Commerce has written:

> The hat-weaving industry is one of the most important in Porto Rico, and it affords employment to a great many people. It centers in the eastern end of the island, where the air is charged with moisture and one finds the greatest abundance of the palms from which the material for the hats is secured. The work is done mainly in the homes by women and girls, and occasionally some old men. The hats are bought by traveling traders, who then market them to the dealers either for export or for blocking and local wear. So large has the demand become for Porto Rican straw hats that the supply of palm leaves is not sufficient, and quantities of the prepared leaves are imported from the Dominican Republic. The Carludovica palm, out of which the Panama hats of Colombia, Venezuela, and Ecuador are woven, grows well on the eastern end of the island. The authorities are contemplating the purchase of seed of the Carludovica for free distribution and to plant on public lands, in order to supply the fibers for making the Panama style of hat in addition to the typical Porto Rican hat.[2]

Imports of woven hat bodies from China have shown rapid increase from 53,400 dozen, valued at $7,400 in 1914 to 203,600 dozen, valued at $70,800 in 1916.[3] In 1919 the total was 207,809 dozen with a value of $37,087. Most of these—80 to 85 per cent—were of a coarse fiber, known as rush hats.

Coarse palm leaf hat bodies for harvest hats are imported from Spain (Malagas) and from Mexico. Penits and other grass and rush hats come from China and the East Indies. Considerable quantities of bamboo hats are imported from Java.

C. ACCESSORY MATERIALS.

The accessory materials used in the manufacture of straw hats were, before the war, almost entirely imported. Bleaching and dyeing materials came from Germany, glue for sizing from France, and silk hat bands from Germany and Italy. When imported leathers were used, they came from Belgium and England. The tips or linings were made from satin produced in this country or in France, and the lace came from England. At present practically all the accessory materials are of domestic production. The American materials are higher in price and in some cases of unsatisfactory quality.

III. PROCESS OF MANUFACTURE.

A. SEWN BRAID HATS.

Bleaching and dyeing.—All the large factories have bleaching departments, and in the case of factories producing women's hats, dyeing plants as well. In bleaching, the braid is immersed in rectangular wooden vats, which contain chemical solutions kept at high temperatures (ca. 170° F.) by steam heat. The process for each lot of braid, including several different kinds of baths, requires from one to two weeks, depending on the kind of braid and the sort

[2] Harris, Garrard: The West Indies as an Export Field. United States Department of Commerce Special Agents Series, No. 141, (1917), p. 254.
[3] China. Maritime Customs; Return of Trade and Trade Reports (1917), Part III; Analysis of Foreign Trade. Vol. II. Exports. pp. 761-763.

of finish desired. The bleaching agents most commonly used before the present war were blankit, a German secret process product, oxalic acid, and peroxides of sodium and hydrogen. Since 1914 zinc dust and bisulphite of soda have been substituted for blankit, and hydrofluoric acid and sulphuric acid for oxalic acid. None of these substitutes have proved satisfactory.

After removal from the vats, an operation accomplished in some of the larger factories by specially designed machinery, the braid is dried in a room furnished with artificial heat, either on a belt conveyor or with the aid of ventilating machinery.

The braid for women's hats is generally dyed instead of being bleached, colored straw hats of all shades being at present more in demand than white "sailors." The dyeing process is similar to that used in textile factories.

Sewing.—After drying, a process requiring one or two hours, the braid is sorted and graded and made up in lots ready for the sewing room. Braid hats are sewed entirely by machine. The sewing machines are power driven and run at a high rate of speed. They are arranged in rows above a shaft, the treadle controlling the starting and stopping device, while a lever operated by the operator's knee lifts and lowers the needle bar. Thus the operator's hands are free to handle the body of the hat and the braid as it unwinds from large spools near by. A small "button," which forms the center of the crown, is used as the starting point, the braid being sewed around and around until the crown is finished, conforming in height and diameter to a model or block set before each operator. The brims, sewed separately and afterwards joined to the crown by other workers, are in sailor hats double. Women's hats of intricate patterns are also made in two pieces.

Sizing—This process consists of stiffening or giving body to the hat. It is accomplished by either one of two methods. Dipping in a hot solution of glue is the simpler process. When stiff hats are desired, such as men's yachting hats and women's sailors, the size is given by dipping. Slop sizing is a combination of the processes of sizing and blocking. The hat body is fitted over the original plaster model used in the sewing room, and the glue, a thin solution, is slopped on with a sponge until the straw has been thoroughly permeated. All women's hats, with the exception of the sailors, are sized in this manner, and also men's hats of flexible brims and crowns.

The sulphur bath.—The glue left on the hat in the process of sizing damages the color of the straw, and hence all hats, except those of dyed braid, are put in a hermetically sealed room and thoroughly fumigated with sulphur in order to restore the original clear straw color. This process requires several hours and is generally carried on overnight.

Pressing.—Pressing is a machine process which gives permanent shape to the hat bodies. After being softened by steam, the hat body is placed in a hydraulic press. The die or form which is used in pressing is cast of spelter from the original plaster model used in the sewing room. The press is heated with steam or gas flames. The hat body is retained in the press for several minutes at a pressure of from 100 to 200 pounds to the square inch.

Finishing.—Finishing is a hand process applied to only the finest grades of men's hats. The hat is placed on a block and covered with

a damp cloth. An electrically heated iron is used to smooth out all irregularities and give a fine, glossy finish to the surface of the hat.

Varnishing.—Women's hats of dyed braid, and also woven body hats which have been dyed, are given a coat of varnish or lacquer after pressing. The varnish is usually applied by hand with brushes, but in some factories it is sprayed on by compressed air.

Trimming.—Trimming, in the case of men's hats, consists in sewing the leather sweatband, the net lining, and the satin "tip" into the inside of the hat and fastening the black silk band around the outside of the crown. This process is invariably done by women. Machines are used in trimming the cheaper grades of men's, boys', and children's hats. Most women's hats produced in large factories, i. e., the medium and low priced hats, are sold to the jobber untrimmed. A few women's sailor hats are trimmed in the same fashion as men's hats and in addition a considerable quantity of "ready-to-wear" hats, varying from year to year according to the changes of fashion, are trimmed with plain sashes and ornaments.

Women's hats are inspected after pressing and the shapes which have been damaged in handling are either steamed and pressed or thrown out. Men's hats are inspected and graded after trimming. The final processes in both cases consists in packing the finished hats in paper boxes (the so-called bandboxes), and then in either wooden cases or in the corrugated paper cartons which in later years have been largely substituted.

B. WOVEN-BODY HATS.

The bleaching, dyeing, pressing, finishing, and trimming of woven hat bodies are processes similar to those performed upon sewn-braid hats, described above. Some of the processes, however, are omitted in the case of woven hat bodies. Panama and Leghorn hats, for instance, do not require bleaching. Sizing, also, is a process generally omitted. The important operation of sewing braid is of course entirely eliminated. Hence the labor cost involved in finishing and trimming woven hat bodies is considerably less than that of manufacturing sewn-braid hats. On the other hand, hat bodies are more expensive than straw braid, and hence the materials make up a larger proportion of total manufacturing costs in the case of woven-body hats. The cheapest grades, the so-called harvest hats, are neither bleached, dyed, nor sized. After being softened with steam they are given a permanent shape in hydraulic presses. The brims are trimmed and the raw edges bound by machinery. Sewing machines operating at high speed attach the inside lining and the outer band at the same operation, and the hat is then completed. Such hats are turned out by the thousands of dozens yearly in a few large factories in this country.

IV. DIVISIONS IN THE INDUSTRY.

The total production of straw hats in the United States in 1914, the latest date for which official statistics are available, amounted to about $28,000,000.[1] No distinction was made in the published census returns between men's and women's hats, but an examination of the original schedules shows that the total output was rather

[1] Including $2,475,000 produced in establishments among the other industries.

evenly divided between the two branches of the industry. The value of men's hats amounted to approximately $12,500,000, or 45 per cent of the total production, and women's hats amounted to $15,500,000, or 55 per cent.

The same statistics show that men's hats are usually produced on a larger scale than women's. The total production of shops doing an annual business of $50,000 and over (men's and women's hats) was $20,440,000. Of this amount the value of men's hats was 60 per cent. The smaller shops, those having an annual output of less than $50,000, are either millinery establishments or shops for blocking and trimming Panama and other woven-body hats.

A. MEN'S HATS.

Of men's hats there are two well-recognized divisions: (1) Men's fine hats, including hats selling at wholesale from $9 to $24 per dozen, are mostly sewn-braid hats. Hats of the more expensive braids sell as high as $36 a dozen. The high-grade Panama and Philippine woven hats are considerably more expensive. The hats of this description sell in retail stores at prices ranging from $1.50 to $6 each; and (2) "Medium and low priced goods" consist of men's, boys' and children's hats wholesaling from $1.75 to $6 per dozen. In this class there is included a small quantity of sewn-braid hats made of the cheapest straw braids, but the larger proportion are the coarse woven bodies which, when pressed and trimmed, are sold as "harvest hats." These retail at from 25 cents to $1 each.

Both classes of men's hats are produced on a large scale in well-equipped factories using modern machinery. The output of the representative factories varies from 50,000 to 100,000 dozen hats per year. Some of the firms specializing in "harvest hats" turn out from 150,000 to 200,000 dozen hats annually. The census returns of 1914 showed eight establishments engaged in the production of men's straw hats, with an annual output of over $500,000 each. The total output of these eight firms, which may be distinguished as leaders in the industry, was valued at $7,000,000, or 56 per cent of the entire American production of men's hats. There were 19 other firms which may be regarded as substantial factors in the industry whose output varied from $100,000 to $500,000.

B. WOMEN'S HATS.

Among the firms producing women's straw hats four groups may be distinguished:

(1) Millinery shops which make and trim high-priced hats in small quantities and in individual styles.

(2) Factories turning out medium and low priced untrimmed hats in large quantities. Such hats wholesale at from $8.50 to $30 per dozen, the bulk of them selling at $15 or $18. A few of the largest of these manufacturers in eastern Massachusetts make from 50,000 to 125,000 dozen of such hats yearly. These might be called the staple goods of the women's straw-hat trade.

(3) Factories producing "specialties," new hats of unique shapes, made of fancy braids, selling at a somewhat higher price than the staple goods, viz, $24 to $36 per dozen.

(4) "Kikes." This term is applied to a fluctuating element in the women's hat business which has become of considerable importance in the last 10 or 12 years. The "kikes" are small manufacturers, having no permanent place of business, who carry on the production of hats in rented lofts in large cities such as New York, Chicago, and Boston. Such manufacturers originate no styles of their own, but offer to duplicate at low prices the shapes put out by large factories which have already proved popular. Capital for investment in machinery is borrowed, and braid is secured from importers on credit. The manufacturer and his friends and relatives compose the labor force. In order to rush production, avoiding the restrictions on hours of labor of women imposed by the State laws and in late years by labor organizations, men are generally used for the important operation of sewing the braid. On account of the haste in which the work is done the hats produced in such shops are necessarily of inferior quality, although closely resembling in style and superficial appearance the more expensive hats of which they are copies. Although a few of these manufacturers make large profits and become permanently established in the business, most of them do not succeed, and the percentage of failures is annually large.

The competition of "kikes" has been seriously felt by the large factories in recent years, and the market for women's hats has been somewhat disorganized as a result. In consequence of the keen competition in the production of cheap grades of hats, the larger factories have tended to devote their attention to the production of better grades of hats at higher prices. The tendency is shown by the decrease in the quantity of hats produced in several large establishments in the last two or three years without, however, a corresponding decrease in the value of their annual output.

Practically all of the factories engaged in making women's straw hats also make trimmed hats for fall and winter wear of velvet, satin, and felt. Straw hats, however, are always the main product. By making a subsidiary product of other materials it is possible to utilize a part of the factories' labor force and plant during the summer and early fall.

The census schedules filed by manufacturers in 1914 show 35 or 40 firms making women's hats, whose business amounted to over $50,000 yearly. Of these, 5 establishments had an annual production of over $500,000, and 7 others ranged from $300,000 to $500,000. The business of the 12 leading firms was $5,300,000, or about 35 per cent of the total value of women's hats produced in this country.

C. REASONS WHY WOMEN'S AND MEN'S HATS ARE MADE IN SEPARATE ESTABLISHMENTS.

Women's and men's straw hats are almost invariably produced in separate establishments and should be regarded as representing different branches of the industry. Both branches use the same materials, for although the braids of which women's hats are composed show more variety in material and in style of plaiting, yet they are imported from the same countries as braids used in men's hats and fall under the same tariff classification.[1] The same is true of woven hat bodies.

[1] Ramie fiber braids, of which the importations amounted in 1917 to $4,000, are an exception to this statement.

Other materials, with the exception of trimmings, are identical. The same sewing machines and processes are used in both sorts of factories; the labor force operating these machines could easily adapt itself to the production of either variety of hats. Although the firms making women's hats in general operate on a smaller scale, yet the representative or leading firms are not much inferior in the amount of capital invested or in the value of their annual output to corresponding firms in the men's trade.

The explanation of the separation of these businesses in spite of many "communities of interest" seems to lie in differences in the character of the demand for their products. Their production problems are similar, but their selling problems are different. The distinctive characteristics of the demand for women's hats are: (1) The great variety of styles which are wanted. No woman wants a hat exactly like her neighbor's, whereas, men show a tendency to uniformity in headgear as well as in other articles of dress. (2) The suddenness of changes in styles. In men's hats a considerable standardization of shapes and trimmings has been attained, and the standard styles remain fairly constant from year to year. Retailers can carry over their stocks of men's straw hats which remain unsold, with a fair chance of getting rid of them in the following season. It would be almost impossible to sell women's hats except in the same season in which they are produced. Because of the risk of changing styles, women's hats must be produced and delivered within a short time after the date of ordering. This period may be as long as 30 days for sample orders at the beginning of the season, but it shortens to a week or 10 days at the height of the busy period in the spring. In the case of men's hats, six or seven months may elapse between the receipt of the order and the delivery of the goods.

The consequence of these characteristics of demand is that in making women's hats attention must be concentrated on the development and production of fashionable styles. The ability to predict in advance the fluctuations in fashion is a large element in the successful management of a women's hat factory.

There is great seasonal fluctuation in the production of both women's and men's straw hats, but nothing would be gained in this respect by the combination of the two varieties in the same establishment. The busy season in the men's hat trade, although somewhat more extended, covers the same months as the season of greatest production of women's hats. Consequently, the varieties would conflict rather than supplement each.

V. SEASONAL CHARACTER OF THE STRAW-HAT INDUSTRY.

The season of production in the case of women's straw hats extends from about the middle of November until May 1. Production on early orders begins early in November, but the factories are not generally working up to normal capacity until December 1. The so-called "regular" season comes to a climax and ends at Easter time, or about April 15. The "summer" season, or "after" season, extending from Easter to about June 1, in which sport hats and novelties for summer wear are made, has of late years become of increasing importance.

No women's straw hats are produced between June 1 and November 1. Consequently, the sewing machines in hat factories, which are

used only on straw hats, are idle during the summer months.[1] The women and girls who operate these machines must then find some other employment. In the case of large Massachusetts factories, the operatives return to their homes in New England country towns. Many of them are employed as waitresses in summer hotels. Employees of city millinery shops find it more difficult to get work during the dull season. This fact is perhaps one of the advantages determining the location of the largest women's straw-hat factories in New England villages.

Men's hats are produced through a longer season. Salesmen go out during the last of July or early in August to take orders for the following season. Production begins on these orders as fast as they come in, and the factories are usually running at normal capacity about November 1. Shipments are made on original orders in February and March to the Southern States and in March and April to northern dealers. Production on duplicate orders generally keeps the plants busy up to July 1. They are generally practically idle for a full month in the middle of the summer, only a small part of the labor force being retained to make repairs, etc.

VI. MARKETING METHODS.

[illegible] women's hats are sold through jobbers and wholesalers. The cheaper hats (those designed for the country trade (i. e., for sale in small towns and villages)) are marketed by this method exclusively. The higher grades of hats are sold by either of two methods: (1) through jobbers and wholesalers, (2) directly from factories [illegible] the growth of the millinery business done by large [illegible] stores the second method has increased in importance. [illegible] almost one-half of the city trade is supplied directly from [illegible]

[illegible] similar situation exists in the men's hat trade. Men's [illegible] those wholesaling from $9 to $24 a dozen, are now [illegible] directly to retailers. Even the imported hats are to [illegible] retailers in this country by representatives of [illegible] manufacturers. This statement, of course, refers only to [illegible] the largest buyers such as department stores and [illegible] men's furnishings. Foreign hats are distrib- [illegible] through importing wholesalers. Medium [illegible] domestic manufacture are usually marketed [illegible] commission basis. The method, how- [illegible] are being made by [illegible] directly with the retailers.

[illegible] FORCE

[illegible] has already been shown, is [illegible] fluctua- [illegible] The census sta- [illegible] wage earners em- [illegible] in the busi- [illegible] month of [illegible] February to [illegible]

[1] [illegible] The [illegible]

In typical months of the busy season, the men compose about 40 per cent of the labor force, but the proportion varies considerably in the summer months. Men in general are more constantly employed than women. Repairers, firemen, watchmen, etc., are kept busy in all seasons. Men engaged in pressing, flanging, and in packing in women's factories are transferred from the straw to the felt hats in the slack season. The operation of sewing straw braid, on the other hand, employs women exclusively, and in the slack season of straw-hat production they have no work.

Skilled labor.—Operations requiring skilled labor are sewing, blocking, pressing, finishing, and trimming. The first and last of these are always performed by women. Sewing is the most skilled operation, at least one season being required before normal proficiency can be attained. A second season generally adds considerably to an operator's skill. A number of new girls are taken into the factories every fall as learners and are paid day wages until they have acquired enough skill to earn more at a piece-work rate. Blocking, pressing, and finishing are men's occupations, which are paid at piece-work rates. Reasonable proficiency can be acquired in any of these processes in a few months. According to estimates furnished by representative manufacturers, the proportion of laborers who might be called skilled is about 75 to 80 per cent of the entire number of wage earners employed.

VIII. EXPORT TRADE.

Although American manufacturers have shown little interest in selling to foreign countries, the total volume of export trade has been considerable, amounting to from 5 to 7 per cent of the total domestic production. Canada is the chief market; others of less importance are Cuba, Mexico, Panama, Colombia, and Argentina.

The statistics of American exports of straw hats do not give a clear impression, either of the amount of the trade or of its tendencies in recent years. The principal class under which straw hats are exported is "Manufactures of straw and palm leaf," comprising men's hats, and bleached and dyed straw braid, as well. Prior to July 1, 1917, women's straw hats were not separately classified, being returned under "All other articles." A separate class entitled "Artificial flowers and millinery" was made in the statistics for 1917, comprising, among other articles, the women's straw hats exported in that year. The value of the exports of this class was $1,513,300.[1]

The following table shows the exports of manufactures of straw and palm leaf to the principal countries in the years 1910–1920:

Year.	Canada.	Latin-American countries.	All other.	Total.
1910	$460,986	$111,396	$52,948	$634,330
1911	553,789	103,866	67,195	724,850
1912	642,908	117,267	78,480	838,115
1913	705,125	94,646	88,890	886,661
1914	651,085	49,508	98,816	799,507
1915	508,899	64,620	108,973	680,492
1916	414,978	169,433	106,753	691,164
1917	510,594	368,194	172,054	1,050,842
1918[2]	164,216	663,247	22,246	849,709
1919[2]	264,263	565,171	95,996	926,430
1920[2]	217,087	1,198,116	187,738	1,602,941

[1] A new classification of commodities exported, approved May 25, 1917, does not assist in obtaining more accurate information regarding the exports of straw hats. The new classification is as follows: Hats and materials for: For men and boys: felt; all other. For women and children: untrimmed; trimmed.

[2] Calendar years.

The average annual exports for the three war years, 1915–1917, were $807,500, showing an increase of 7.5 per cent over the annual average for the five prewar years, $750,000.[1]

The exports to Canada, according to the above table, show a decreasing tendency, the average per year being $477,500, 1915–1917, and $605,900 for the years 1910–1914. But the Canadian statistics of imports of straw hats from the United States give an entirely different impression.

CANADIAN IMPORTS OF STRAW HATS FROM THE UNITED STATES.[2]

1910	$580,150	1916	$1,092,891
1911	662,323	1917	1,545,583
1912	872,774	1918	1,695,307
1913	1,185,874	1919	1,842,950
1914	1,164,072	1920	1,083,426
1915	1,129,878		

The difference between the American and Canadian statistics, amounting in 1917 to roughly $1,000,000, represents the value of women's straw hats exported from the United States as millinery.[3]

The Latin-American trade, while of small importance as compared with the Canadian, has shown tendency to increase since 1914. The exports of manufactures of straw and palm leaf to Latin-American countries averaged in yearly value $94,900 for the years 1910–1914 and $204,000 for the years 1915–1917.

The Tariff Commission has received the following statement from an exporting house regarding the South American trade:

Women's straw hats constitute the largest percentage of hats shipped from the United States to South America. They are mostly made from sewn braids. Of these the greatest number are blocked, but not trimmed, though there is a fair quantity shipped already trimmed. As far as we know there are very few harvest hats or men's hats shipped from this market to South America.

The European war has had the effect of increasing the exporting of American straw hats to South America. American hats are undoubtedly being exported in larger quantities now than in the years of 1913 and 1914. While it is early for us to compare the season of 1917 and 1918 with the season of 1916 and 1917, we are under the impression that 1917 and 1918 will show an increase over the shipments of 1916 and 1917.

There is not a very large business done in the shipment of hats from there to South America, while, on the other hand, there is a very large business done in the shipping of both natural and dyed braids, which are made into men's and women's hats.[4]

We understand that in South America there are over 1,200 manufacturers of hats. It is undoubtedly cheaper for them to import the braids than to import the hats, which are very bulky, and, in proportion to their value, pay a great amount of freight. Incidently, the element of style, which changes so frequently, makes it desirable for any market to make their own hats.

Italy, before the war, did a fair amount of business with South America, in both woven body hats and also sewn braid hats, both for men and women.

In the West Indies there is a growing business in a cheap grade of women's hats. The Cuban market calls for sewn braid hats of a good quality. There is also a fair demand for the body hats, known as the Japanese paper Panama, a hat which is brought from Japan and blocked in this country.

American manufacturers are not as a rule enthusiastic about the export trade at present, nor are they optimistic regarding the possibilities of continuing and developing it after the war. In reply to

[1] Reexports of straw hats (exports of foreign merchandise) averaged in value $96,450 annually in the years 1915–1917, and $96,870 in the years 1910–1914. The chief countries to which foreign straw hats are exported are the United Kingdom, Cuba, Colombia, and Canada.

[2] Canada. Trade Reports of the Department of Customs.

[3] The value of artificial flowers and millinery exported to Canada amounted in 1917 to $1,118,200.

[4] The United States Commerce and Navigation Reports show 61,708,001 yards of straw braid reexported in 1917 and 36,277,200 yards in 1916.

inquiries, the Tariff Commission has received the following statements from representative manufacturers:

We ourselves have had several inquiries (concerning exports to foreign countries), but are doubtful if we could handle the business properly, so did not care to take it on.

We have had many inquiries for goods from foreign markets but do not care to develop this trade. The home market is good enough for us.

We always exported to Canada and have since the war began sold a few hats to Australia and South American countries. By selling reliable goods at low prices we hope to be able to continue this trade after the war.

We have no interest in export trade.

Our Canadian sales are good and we are pushing this business. We would like to do business in South America and Australia but do not find the outlook very promising.

The war has brought us some foreign business from Australia and quite some from Canada. The Australian demand in volume is mostly for inexpensive hats and in this line competition is particularly strong from England.

Undoubtedly the labor scale, from what brief information we have, is lower in England than it is here, which we presume will make it much more difficult to get export business after the war. The only possible chance we would have to keep up a certain proportion of this foreign business would be owing to the great diversity of shapes that we show as compared with what they show in England. (From a manufacturer of women's hats.)

We do not expect foreign trade to continue after the war, the chief reasons being duty on material and high wages preventing large exports.

Do not believe the American manufacturers can hold export business after the war; England and Italian exporters are more familiar with the demand and customs of the South American market and are better organized for that business.

IX. COMPETITIVE CONDITIONS.

Kinds of hats imported.—The imports of straw hats are classified for revenue purposes into two groups:

1. Hats, blocked or trimmed.
2. Hats, not blocked or trimmed.

In the first group are comprised all finished hats; in the second, semimanufactured products, viz., woven hat bodies in the rough. The latter must go through processes of bleaching,[1] dyeing, pressing, finishing, and trimming in American factories before they are ready for sale. The finished or trimmed hats, on the other hand, are ready for sale when imported and compete directly with the American-made straw hats. Hence, attention must be confined to the second group alone, i. e., trimmed hats, when discussing foreign competition.

Why women's hats are not imported.—It should at once be noted that practically no women's finished hats are imported into this country. With the exception of a few models brought each year from Paris, all straw hats worn by American women are of domestic manufacture. The explanations of this fact given by manufacturers and importers in answer to inquiries by the Tariff Commission may be summarized as follows:

1. Production in this country is more standardized. In foreign countries, women's hats are more usually custom-made products. American hats show more uniformity in shapes and hence can be turned out in large quantities at relatively low cost.

2. The shortness of the season and the necessity of making quick deliveries makes foreign competition difficult. As pointed out above, styles change suddenly, and in the height of the season goods are

[1] Some of the imported hat bodies, such as the Japanese imitation Panamas and those used for harvest hats, do not require bleaching.

[illegible] from resent of others. A manufacturer of [illegible] has written to the Tariff Commission:

"[illegible] make it or the [illegible] much more satisfactory when [illegible] the [illegible] the better it is for the industry.

"[illegible] of [illegible] are [illegible] a soft water—they must be sold [illegible] they are poor while fresh.

"[illegible] of [illegible] women's hats was summarized by a [illegible] Trade Association at the tariff hearings [illegible]:

"[illegible] in the [illegible] manufactured in this country. Some women [illegible] and [illegible] with them it is the trim. The style in which [illegible] women's hats are [illegible] the time [illegible] have changed before they are here. The [illegible] its styles by taking some of the ideas that have spoken [illegible] and [illegible] made within a week or two before [illegible] before [illegible] to attempt to make their hats until [illegible] come over from the other side and indicate what [illegible] wear. Then they make in their studios. I think I [illegible] in this country [illegible] some Fifth Avenue milliner will pay three or [illegible]

[illegible].—The imports of finished straw [illegible] of trimmed are almost exclusively for men's [illegible] inclusive the value of the annual [illegible] has averaged $[illegible]. The American product [illegible] compiled from the schedules of the census [illegible] The proportion of the home market [illegible] according to the calculation is 7.37 per [illegible] The [illegible] caused by the importation of finished hats [illegible] market was first noticeable about 1910. A representative [illegible] manufacturers stated before the Ways [illegible] in 1913:

"[illegible] the purpose did not seriously interfere with our home industry prior [illegible] there was a strong desire on the part of the hat retailers to purchase Italian [illegible] manufacturer need and naturally reflected the same [illegible] They were sold over the same counters and bought by the [illegible]

The character of foreign competition in the hat industry was again [illegible] at the 1913 tariff hearings:

"[illegible] France never made straw hats that were used in this country [illegible] People almost rarely wore straw hats, strange as it may [illegible] wear them they were shapes and fashions that nobody [illegible]

Methods of production in foreign countries.—The countries from [illegible] straw hats for men chiefly come are Italy and England. In the case of these countries is the factory system used to the [illegible] as in the United States. The Italian [illegible] of production, were described by the United States consul [illegible] 1912, as follows:

"[illegible] are upward of 100 factories devoted to braid work and [illegible] and unfinished hats. Only some 4,000 persons are [illegible] The outside workers are listed under two [illegible] 65,000 are "pigionali," i. e., live

[illegible]

[illegible] Tariff hearings, 1913, Vol. V, p. 4091.

in rented houses, usually near some factory, and 19,000 are "coloni," i. e., tenants of small farms worked on shares. More than 56,000 women and 26,000 girls under age are engaged in straw work. They work for the most part at home, and the making of the hat braid is, in the case of the coloni, done in addition to the usual work of the day.[1]

In England hats are made partly in homes and partly in factories. The manufacturers give out braid and the sewing is done by women and children in their homes near the factory. The rough hat bodies are then taken to the factory to be blocked and finished. In many cases the hats are sent back to the outworkers to be trimmed. In some of the largest factories all processes are now carried on under one roof, as in this country. Machinery of the same design as that found in American factories is used in England for sewing and pressing hats.

Lower costs abroad.—It is the opinion of the American manufacturers that the prewar conditions of production gave foreign producers the advantage of lower costs. The following quotation is taken from a brief submitted by the Straw Goods Association at the Tariff Hearings in 1913:

> Considerable effort has been made to obtain the exact manufacturing cost of sewed-braid hats, both trimmed and untrimmed, and representatives of several hat manufacturers went abroad for the purpose of investigating the straw-hat business as conducted in Europe, and to learn why they could manufacture hats so much cheaper than we could. They went through various hat factories and found them equipped equally as well as the straw-hat factories of the United States, and with all the modern appliances and machinery. An operator is able to make just as many hats over there as here. The work is all piecework, and, while unable to obtain the precise piecework price of hats, they did find that the average labor cost price per dozen was about 35 per cent of the cost price in the United States. This in particular applies to Italian factories, where the labor was in some instances about 25 per cent of what is paid in the United States. Indeed, the price of the sewed-braid hats was so atttractive that several American straw-hat manufacturers now import these hats in an untrimmed state, finding that these hats can be landed in the United States, all charges paid, cheaper than they can be made in their own factories.[2]

Much of the braid used in the production of Italian hats is a product of native straw plaited by peasant women in the region where the hats are made. England imports almost the entire supply of straw braids used in her hat factories, but her manufacturers have the advantage of free entry of this and other materials. In the United States, braid pays 15 or 20 per cent duty, according as it is bleached or unbleached. There is a duty of 15 to 25 per cent on glue, 7½ to 25 per cent on thread, and 45 per cent on silk hatbands. The leather sweatbands used in English hats are of domestic production; those used in the better grades of American hats, before the war, were imported, paying 30 per cent duty. Representative American manufacturers have expressed the opinion that the difference in the cost of production between American and foreign-made hats was fully equalized by the 40 per cent duty imposed by the tariff act of 1913.

Better seasonal distribution.—A possible further advantage of English and Italian manufacturers is to be found in better seasonal distribution of production. Both Italy and England had before the present war developed export trade in countries in the southern as well as in the northern hemisphere. Thus they were enabled to

[1] U. S. Commerce Reports, Apr. 11, 1912. [2] Tariff Hearings, 1913, Vol. V, p. 4997.

balance the slack season in one market with the busy season in another, securing an all-round demand for their goods. Italy not only exported to the United States, but also supplied a large proportion of the straw hats imported into Peru, Brazil, and the Argentine Republic. Some Italian hats were sent to Australia and South Africa.[1] These latter countries however, were chiefly supplied from England.

The English exports of straw hats to countries south of the Equator—Argentina, Cape of Good Hope, Transvaal, Victoria, and New South Wales, amounted in the years 1913–1916 to between 26 and 27 per cent of the exports to all countries for those years.[2]

Kinds and grades of foreign hats sold in United States.—The foreign straw hat most popular in the American market is the English sennit hat of the yachting shape. Such hats, retailing at $1.50 to $2 each, were until last year (season 1916–17) strong competitors of the domestic product. The buyer of men's straw hats for a large department store states:

> In the years 1914–1916 the English hat retailing at $2 was decidedly better-looking, superior in details of style and of manufacture and was more durable than the American hat selling at the same price. In addition it had the prestige of a foreign label.

Manufacturers and importers differ as to the importance of the various factors above enumerated, in determining the sale of English straw hats. The foreign label has been so often counterfeited that it has lost much of its importance as a selling factor. The details of style of the English hats, such as the height of the crown and the width of the brim, are often determined by the American retailers when giving their orders. Certain peculiarities of the finish of the English hats are distinctive. They are generally made of whole straw and hence are heavier than the American split product. The English hat on this account does not need as much sizing and hence stands damp weather without becoming soft or sticky. There is probably more hand work done on English hats, in blocking and finishing, than on the American hats selling at comparable prices.

X. COMMENTS AND SUGGESTIONS AS TO TARIFF CLASSIFICATIONS.

It should be noted that two general classes of commodities are taxable under paragraph 335: (1) Materials such as straw braid, etc., used in the manufacture of straw hats and (2) hats manufactured from these materials. Both the materials and the hats are again split up into two subdivisions; on the basis of the stages in process of manufacture through which they have passed. Thus dyed braid is taxed 5 per cent higher than undyed and blocked or trimmed hats 15 per cent higher than those not blocked or trimmed. Consequently we have the following scale of duties:

	Per cent.
On braids of straw or similar materials:	
(*a*) If not dyed or bleached	15
(*b*) If dyed or bleached	20
On hats of straw or similar materials:	
(*a*) If not blocked or trimmed	25
(*b*) If blocked or trimmed	40

[1] The exports of Italian hats were valued at $768,900 in 1915. Of this amount $58,650 went to Argentina and $68,050 to Brazil. Movimenti Commerciale, 1915.

[2] Trade of the United Kingdom with foreign countries. 1913, 1914, 1915, and 1916.

The following changes in the act of October 3, 1913, have been suggested by manufacturers and importers:

(1) That sewn-braid bodies should be distinguished from woven-hat bodies, in the class "not blocked or trimmed." A higher rate of duty should be imposed on the sewn-braid bodies than on woven-braid hats since none of the latter are produced in the United States.

(2) That the classification "Hats, blocked or trimmed" should be subdivided into (*a*) hats, blocked; (*b*) hats, blocked and trimmed, and that the latter subdivision should be dutiable at a higher rate than the former.

(3) That a distinction should be made in the class "Hats not blocked or trimmed" between bleached and unbleached bodies, in order that the American manufacturers might be protected against the importation of the Japanese imitation Panama hats, which require no bleaching.

(4) That the duty on straw braid, not bleached or dyed, should be removed, and the present ad valorem duty on bleached and dyed braid should be changed to a specific duty giving an equivalent amount of protection.

(5) That men's hats and women's hats should be separately classified and should be dutiable at different rates, because there is practically no foreign competition on women's hats.

Hats not blocked or trimmed.—An importing firm suggests that the classification "hats not blocked or trimmed," should be subdivided into two groups (1) sewn-braid bodies; (2) woven-body hats. A higher rate of duty should be imposed on the sewn-braid bodies than on woven-body hats, since the latter are not produced in this country. The sewn-braid body, on the other hand, is the standard product of American factories. Moreover, the American manufacturers need a duty on sewn-braid bodies to offset the duty which they have to pay on the imported straw braid.

Blocked and trimmed hats.—The same firm suggests further that blocked and trimmed hats should not be included in one class. A higher rate of duty should be imposed on hats which have been both blocked and trimmed, than on those which have merely been blocked. The former have required greater expenditure of labor and also the trimmings, if imported as before the war, are dutiable. Therefore, in order to secure a more scientific adjustment of duties, blocked and trimmed hats should be placed in separate classes, and a differential should be imposed upon the trimmed hats.

Bleached and unbleached hat bodies.—A distinction should be made in the tariff laws, according to the view of a large manufacturer. At present the woven hat bodies come in under one classification; namely, "hats not blocked or trimmed," and are dutiable at 25 per cent ad valorem. The Japanese imitation Panamas, this manufacturer believes, are particularly dangerous competitors of the American sewn-braid hats, and he thinks that since Japanese hats do not require bleaching, they should be dutiable at a higher rate of duty than other woven hat bodies.

Duties on straw braids.—A firm engaged in dyeing and bleaching straw braids believes that the present ad valorem duties (20 per cent on braids dyed, bleached, colored, or stained; 15 per cent on braids not dyed, bleached, etc.) does not present a scientific method of dis-

crimination between the two sorts of braids. The cost of dyeing or bleaching the braid is not dependent on the *value* of the braid, but upon its bulk and weight. Expensive braids often cost less to bleach or dye than cheap braids, but under the present law the amount of protection afforded to bleachers and dyers (represented by the differential of 5 per cent) is always in proportion to the value of the braid, and not necessarily in proportion to the cost of dyeing or bleaching. In general, the present law gives excessive protection to bleachers and dyers when treating the expensive braids, and not enough protection in dyeing cheap, bulky braids.

A specific duty laid either according to units of weight or measurement, this firm submits, would be more equitable to dyers and bleachers. Such a system, however, might work injustice to manufacturers of sewn-braid hats, imported hats being dutiable at ad valorem rates. A suggested method of improving the law, aiding the bleaching and dyeing firms, and manufacturers, as well, is the abolition of the duty on braids in the rough (i. e., braids not dyed, bleached, colored, or stained). Then, a specific duty might be imposed on all dyed and bleached braids imported, to protect American firms engaged in the business of dyeing and bleaching.

A number of large manufacturers making men's and women's hats have expressed themselves in favor of the removal of the duties on straw braids. No domestic industry is protected by these duties, since no straw braid is at present produced in this country. Manufacturers of straw hats, however, are burdened on account of the duty with higher cost in competing with foreign manufacturers, both in the domestic and foreign markets. The higher costs of braid to the manufacturers do not consist merely in the amount of the duty paid by importers, but a series of other costs are also included. The necessity of paying a duty on raw materials makes the importers' business more complicated and consequently makes it necessary for them to operate on a larger margin of profit. Drawbacks of duties paid on imported braid are indeed allowed to manufacturers when straw hats containing such braids are exported, but the process of recovering the amounts due is so cumbersome and attended by so many delays that manufacturers feel hardly repaid for the trouble involved.[1]

A few of the manufacturers favor the retention of the duties on straw braids, because they anticipate that if the braids were put on the free list the next step would be a lowering of the duty on the finished hats. The reduction might be more than enough to compensate for the lower cost of braid. They regard the present tariff situation in their industry as satisfactory and their motto is "Let well enough alone."

TARIFF DISCRIMINATIONS.

The only important cases of discrimination against American straw hats in foreign tariffs are found in Canada and Australia. In the former country English hats are dutiable under the British preferential tariff at 25 per cent ad valorem; American hats pay the general tariff rate—37½ per cent. The Australian tariff admits English hats at 35 per cent ad valorem and imposes a duty of 40 per cent on American hats.

---

[1] Drawbacks repaid on account of straw hats exported amounted to $13,919 in 1917.

Court and Treasury Decisions.

Act of 1883.

In 1883 the rate on bonnets, hats, and hoods was made 30 per cent ad valorem and that on materials 20 per cent. The enumeration of straw and other materials was followed by the words "any other substance or material."

The hat trimmings cases arose under this act. Ribbons of silk and cotton, silk chief value, known as "trimmings" and used exclusively or chiefly as trimmings for hats, bonnets, and hoods, were held dutiable as hat trimmings and not as manufactures of silk.

So also were trimmings of silk and metal, metal chief value, and piece goods known as "chinas" and "marcelines" chiefly used for lining hats and bonnets. There was no restriction upon the kind of material; if they were trimmings for hats and were chiefly so used the provision applied, whatever the material. (Hartranft *v.* Langfeld, 125 U. S., 128; Robertson *v.* Edelhoff, 132 U. S., 614; Cadwalader *v.* Wanamaker, 149 U. S., 531; Walker *v.* Seeberger, 149 U. S., 541; Hartranft *v.* Meyer, 149 U. S., 544; Meyer *v.* Cadwalader, 4 Fed., 19; Fisk *v.* Seeberger, 38 Fed., 718; Walker *v.* Seeberger, 4 Fed., 724.)

The words "not specially enumerated or provided for in this act" were interpreted by the Attorney General as applicable to articles of the description mentioned in the provision and not to the material from which such articles were made. (17 Opin. Att'y Gen., [illegible]

of woven willow with a backing of thin cotton cheesecloth glued vere held exempt from duty under this act as sparterre. 6 (T. D. 11691).)

ACTS OF 1890.

t of 1883 was amended by the act of February 18, 1890, f restriction (*a*) by changing the general phrase "any other e or material" to "any vegetable material"; (*b*) by eliminat- trimmings, and tissues from the enumeration of materials; by substituting "fit only for use in" for "used for" before s "making or ornamenting hats, bonnets, and hoods." Oil- hatsweats was held dutiable as oilcloth and not as material (G. A. 84 (T. D. 10393).)

were further restrictions in the general tariff act of that year. ific provision for hats, bonnets, and hoods was omitted; s "any vegetable material" were eliminated; so were "flats, heets, and squares" and also "hair and whalebone" as ma- nd "braids, plaits, laces, and similar manufactures com- straw, chip, grass, palm leaf, willow, osier, or rattan suit- making or ornamenting hats, bonnets, and hoods," were ed to the free list.

urts held that it was sufficient to make the paragraph e if the "predominant and characteristic component" of those enumerated. Schiff *v.* U. S., 99 Fed., 555, holding l straw braids and silver straw braids composed chiefly fiber, the remainder being metal, cotton, and glue, to be as manufactures in part of metal and not free as braids or hats.

w words "similar manufactures" were given a liberal inter- . Plateaux or "flats" consisting of braids or plaits of straw woven together in an oval form and used for making hats, which were manipulated into the desired form and r wired and then trimmed, were declared not to be braids but were held to be "similar manufactures" composed of l suitable for making hats, and therefore exempt from duty an dutiable as manufactures of straw. (U. S. *v.* Bacharach, 990; also Worthington *v.* U. S., 86 Fed., 118.)

ovision for braids composed of straw was held to include straw and cotton, straw constituting more than 71 per uantity and about 75 per cent in value. (U. S. *v.* Rheims Fed., 1020, affirming 154 Fed., 865.)

for hats composed in part of materials not enumerated in the visions were held not exempt from duty although known in e as braids for hats. (G. A. 4036 (T. D. 18723).)

ACT OF 1894.

the act of 1894, which reenacted the provisions in the act braids of Cuban bast were held exempt from duty as braids l of chip and not dutiable as braids of vegetable fiber. G. T. D. 16424). And the word "suitable" in the phrase "suit- making or ornamenting hats, bonnets, and hoods" was held t free entry to such braids as were suitable for the purposes

specified in the particular provision, and raffia braids not found to be so suitable were held dutiable as manufactures of grass. (G. A. 3529 (T. D. 17267).) *Braids of bast, silk, and gum, silk chief value,* held dutiable as silk braids. (G. A. 3584 (T. D. 17393).)

Hatbands of cotton held dutiable as trimmings or as galloons according to the width, being galloons when less than 1 inch and trimmings when 1 to 2½ inches wide. (U. S. *v.* Graef, 127 Fed., 688 (T. D 24975), affirming G. A. 4991 (T. D. 23280).)

Plaits woven into sheets in the form of plateaux or matting were held not entitled to classification as "braids, plaits, laces, or similar manufactures." (G. A. 4013 (T. D. 18615).)

ACT OF 1897.

In 1897 the hat material provision was restored to the dutiable list. Braids, etc., bleached, dyed, colored, or stained, were made dutiable at 20 per cent ad valorem, and those not bleached, dyed, colored, or stained at 15 per cent. Willow sheets or squares were again enumerated with braids, plaits, and laces, and the words "similar manufactures" were stricken out. The provision in the free list for sparterre was also eliminated.

The provision for manufactures of ramie in paragraph 347 of the act of 1897 was held to be merely a general catch-all clause inserted with the intention of embracing articles omitted from other provisions in the act, and to be less specific than the provision in paragraph 339, for braids of vegetable fiber and braids of ramie were held dutiable under paragraph 339. (United States *v.* Rosenberg, 145 Fed., 343; followed in G. A. 6280 (T. D. 27062), as to braids composed wholly or in chief value of ramie.)

Hats, bonnets, and hoods composed of straw, chip, grass, palm leaf, willow, osier, or rattan, whether wholly or partly manufactured, were enumerated in the same paragraph at 35 per cent ad valorem if not trimmed, and at 50 per cent if trimmed. The terms "grass" and "straw" were restricted to those substances in their natural form and structure; the separated fiber was expressly excluded.

The insertion of the word "wholly" materially restricted the provision and was held to limit braids, plaits, laces, and willow sheets or squares to those composed wholly of the enumerated materials. In accordance with that construction, straw lace sewed or bound with cotton thread of small relative cost was held not made wholly of straw and therefore excluded from the provision. (Schmitz *v.* U. S., 146 Fed. 127; also G. A. 6364 (T. D. 27343).) But a small amount of cotton thread used only for temporarily tying the ends of braids to prevent them from unraveling was held not sufficient to remove the articles from the provision for braids wholly of straw. U. S. *v.* Schiff, 145 Fed., 1023, affirming 140 Fed. 63; U. S. *v.* Bacharach, *supra,* was distinguished and rectangular strips about 18 by 32 inches in dimensions, commercially known as "plaits" or "wide braids," were held dutiable as straw braids or plaits suitable for making or ornamenting hats and not as hats partly manufactured.

Miniature Mexican hats about 3 inches in diameter, made of straw and trimmed with colored cords, held dutiable as manufactures of straw. (G. A. 4153 (T. D. 19414).)

bonnets, and hoods, the bodies composed wholly of straw, chip, ılm leaf, willow, osier, or rattan, or of a combination of these ces in chief value, held, if trimmed, dutiable at 50 per cent em, irrespective of the value of the trimming as compared e value of the article without the trimming. (G. A. 4525 1502); G. A. 5734 (T. D. 25440).)

na straw hats with stitched-leather lining or sweatbands and r use except that they were without the outer crown band r other material were held dutiable as trimmed and not as ıed hats. (G. A. 4841 (T. D. 22727).)

an hats of plaited and braided bleached or unbleached and colored straw, the base of the crown and outer border of the ing trimmed with wide ornamental bands of the same or material as the body of the hats, held dutiable as trimmed as untrimmed hats. (G. A. 4842 (T. D. 22728).)

hats, so-called, held to be untrimmed hats composed of grass (Abstract 23388 (T. D. 30645).)

ux circular in form and slightly convex, but nearly flat in ith the appearance of plain, round mats of braided straw ıout the crown and untrimmed, the material of which was y the evidence to be so constructed as to permit of being into hats without adding any new material, and practically or any other purpose, were held dutiable as hats composed partly manufactured and untrimmed. This classification ıanged by the use of two plateaux in the making of a single chiff *v.* U. S. 2 Ct. Cust. Appls., 89 (T. D. 31634), affirming 81 (T. D. 27718).)

sheets or squares, one surface of which is composed of narrow willow, called chip, and the other surface of bleached cotton d dutiable as manufactures of chip and not as willow sheets es composed wholly of chip straw, etc. (G. A. 4152 (T. D. see also Abstract 21299 (T. D. 29790).)

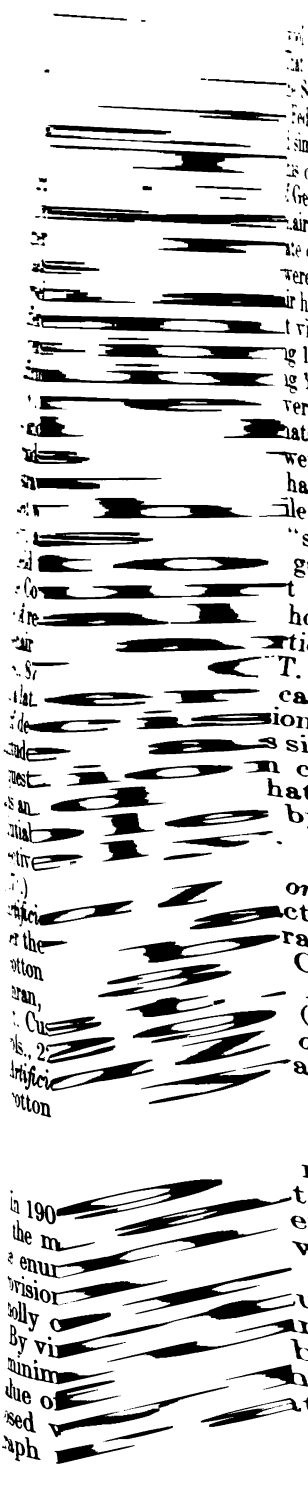
for hats, bonnets, or hoods composed wholly of dyed chip and ited straw held to be "in its natural form and structure," leaned, split, and plaited. (G. A. 4617 (T. D. 21861).)

net or nettings cut into narrow strips or small pieces and for use in lining the sides and crowns of hats, being known as strips, and sides, were dutiable as nets or nettings. (G. A. D. 24784).)

fabrics of grass cloth for trimmings and decorations of hats iable as manufactures of vegetable fiber and not as braids of straw or grass in its natural form and structure. G. A. D. 26265).

s in chief value of cotton, ready to be inserted and fastened in e dutiable as partly made wearing apparel of cotton and not factures of cotton. (G. A. 6458 (T. D. 27660).)

was considerable litigation under this act upon hats and mposed of horsehair. In the absence of a specific provision the question was to what enumerated article they bore est resemblance in one or more of the four particulars—quality, texture, or use. At first they were classified by e as articles "composed of wool," by virtue of paragraph ch provided that the word "wool" when used in connection manufactured article of which it was a component material



included "wool or *hair* of the sheep, camel, goat, alpaca, *or other animal*." That construction, however, was overruled by the Circuit Court for the Southern District of New York in Donat *v.* United States (134 Fed., 1023 (T. D. 25113, reversing G. A. 4876, T. D. 22843)) and similitude to silk braids declared the appropriate classification. This classification was followed in numerous decisions by the Board of General Appraisers because of the superior resemblance of the horsehair articles to silk articles and because of the rule that the higher rate of duty controls in cases of equal similitude. Horsehair braids were accordingly treated for tariff purposes as silk braids and horsehair hats as silk wearing apparel.

A different view was taken in Paterson *v.* United States (166 Fed., 733, reversing 159 Fed., 320); United States *v.* Rheims Co. (175 Fed., 778, affirming 169 Fed., 662); and Wanamaker *v.* United States (175 Fed. 900, reversing 169 Fed., 664). In these cases similitude to straw braids and hats was held to be the correct classification. Horsehair hat braids were declared to resemble silk hat braids more closely than straw hat braids, but straw hat braids were specifically enumerated while the silk articles were given only a generic enumeration, namely, as "silk braids"; mere specificity rather than resemblance was held to govern.

The Court of Customs Appeals refused to follow this reasoning. Hats of real horsehair were held to bear a closer similitude to artificial horsehair articles than to straw hats. (U. S. *v.* Buss, 3 Ct. Cust. Appls., 87 (T. D. 32357).)

In a later case the Board of General Appraisers followed its original line of decisions and held that horsehair braid hats were dutiable by similitude as silk wearing apparel. (G. A. 7373 (T. D. 32617).) When the question came again before the Court of Customs Appeals such braids and hats were held upon the record in the particular case to be dutiable by similitude to silk braids and silk wearing apparel, respectively. (Zimmermann *v.* U. S., 5 Ct. Cust. Appls., 104 (T. D. 3137).)

Artificial or imitation horsehair braids and hats were also an issue under the act of 1897. They were held to be dutiable by similitude cotton braids and cotton wearing apparel, respectively. (U. S. *v.* Schran, 3 Ct. Cust. Appls., 57 (T. D. 32349); Plummer *v.* U. S., Ct. Cust. Appls., 229 (T. D. 32539); Isler *v.* U. S., 5 Ct. Cust. Appls., 229 (T. D. 34401).)

Artificial or imitation horsehair in skeins or yarn was held dutiable cotton yarn by similitude. (U. S. *v.* Eckstein, 222 U. S., 130.)

ACT OF 1909.

In 1909 real horsehair, Cuba bark, and manila hemp were added the materials for braids, etc., but horsehair was not included in enumeration of materials for hats, bonnets, and hoods. The vision was extended to include braids, etc., when composed either olly or in chief value of any of the enumerated materials.

By virtue of the provision in paragraph 347 of that act, prescribing minimum rate of duty, hats and hoods composed wholly or in chief ue of braids of ramie were held properly dutiable as articles com-ed wholly or in chief value of vegetable fiber under that para-ph rather than as wearing apparel wholly or in chief value of

r other vegetable fiber under paragraph 324. (G. A. 737
2583), of 1912.)
rovision for straw hats trimmed was limited by the Treasury
ient to such as, including the trimming, were composed ir
lue of straw. (Department order, T. D. 31794.)
ourt of Customs Appeals construed the provision to exclude
ming in determining the component of chief value. (U. S.
4 Ct. Cust. Appls., 322 (T. D. 33521), affirming G. A. 7415
3086), and distinguishing Rheims Co. *v.* U. S., 160 Fed., 925,
the phrase "composed wholly or in chief value" in the pro-
the act of 1897 for "hats * * * trimmed or untrimmed
composed wholly or in chief value of the fur of the rabbit,
or other animals" to relate to both trimmed and untrimmed
l to require the trimming to be considered in determining
ponent of chief value.)
ished hat sweatbands, consisting of the grain side of a sheep-
t in the pickled state and tanned, dressed, and finished and
s "skivers," were held dutiable as "sheepskins dressed and
" or as "other leather" paying the same rate of duty and
split leather." (Tilge *v.* U. S., 2 Ct. Cust. Appls., 129 (T. D.
affirming G. A. 7134 (T. D. 31131).)
veats consisting of leather cut to form and ready to be sewed into
ts as sweatbands were held dutiable as manufactures of leather.
U. S., 3 Ct. Cust. Appls., 97 (T. D. 32360), affirming Abstract
T. D. 31450).)
na hats undervalued in the invoice and sent to general-order
unclaimed were held subject to forfeiture, notwithstanding
y was made. When unloaded and placed in general-order
ney were introduced into the commerce of the United States
he meaning of subsection 9, section 28, act of 1909, which
fraudulent invoices made by consignors in foreign countries.
25 Packages of Panama Hats, 231 U. S., 358.)
invoiced as trimmed hats and not shown by the testimony of
witness to consist of trimmed straw hats held dutiable as
ring apparel at 60 per cent ad valorem under paragraph 402,
909, and paragraph 390, act of 1897. (Schmitt *v.* U. S., 5 Ct.
ppls., 312 (T. D. 34523), affirming Abstract 33841 (T. D.

nings 4 inches wide and 1 yard in length, in chief value of straw,
d dutiable under paragraph 422, and not as manufactures of
nder paragraph 463. (U. S. *v.* Ascher Co., 5 Ct. Cust. Appls.,
ersing upon stipulation Abstract 33763 (T. D. 33778) and
ng Abstract 25927 (T. D. 31720).)
made of manila hemp braids, having crowns about 5 inches
l brims measuring between 4 and 5 inches in width, the
ge of the brims having a wire fastened thereto giving firmness
rims and keeping them in the desired shape, the wire being
by black velvet, also used to face or cover the under side of
s, the hats only requiring the insertion of a lining and final
of the brims to make them ready for use, were held dutiable
ed hats at 50 per cent ad valorem under paragraph 422, and
ntrimmed hats at 35 per cent under that paragraph. When
shaped and trimming applied to it, even though such trim-

is very simple, the hat is no longer an untrimmed hat within
ening of the statute. (G. A. 7461 (T. D. 33407).)
d trimmings made from *split straw, some braided or plaited* held to
dutiable as manufactures of straw at 35 per cent ad valorem
r paragraph 463 and not as trimmings composed of vegetable
r under paragraph 349. (G. A. 7469 (T. D. 33510).)
bleached willow sheets with *bleached muslin backs pasted thereto,*
he chief value, were held dutiable as willow sheets unbleached.
stract 24325 (T. D. 31103).)
Hat's hat or bonnet with a cotton or buckram frame or foundation
ered and lined with silk and trimmed with silk ties and rosettes
d fancy straw lace, was held dutiable under paragraph 402 as silk
aring apparel and not under paragraph 422 as a hat or bonnet in
of value of straw. (Abstract 24994 (T. D. 31352).)
Plaits invoiced as laced hemp bands, imported in pieces measuring
eral yards in length and from 5 to 30 centimeters or more in width,
re held dutiable as plaits wholly or in chief value of bleached,
ed, colored, or stained manila hemp and not as manufactures of
emp. (Abstract 25927 (T. D. 31720); followed in Abstract 31626
T. D. 33263).)
Merchandise known in trade as leghorn strips, leghorn braids, or
eghorn plaits and classified as manufactures of straw held dutiable as
unbleached straw plaits. (Abstract 28369 (T. D. 32488).)
Braids composed of chip and straw held dutiable at 15 per cent
under paragraph 409 and protest claiming 20 per cent under the same
paragraph held sufficient. (Abstract 30728 (T. D. 33018).)
Grass cloth consisting of manila hemp or grass sheets unbleached,
suitable for making or ornamenting hats, held dutiable under the
first part of paragraph 422. (Abstract 30819 (T. D. 33031).)
Merchandise invoiced as natural straw bands was held dutiable as
manufactures of straw at 35 per cent ad valorem under paragraph 463, and not
at 15 or 20 per cent ad valorem under paragraph 422. These bands
were declared neither braids nor laces but ornaments or trimmings
of straw, and not dutiable as vegetable fiber trimmings because the
phrase "articles made of straw in its natural form and structure"
does not include articles made of vegetable fibers. (Abstract 32985
(T. D. 33560).)
Raffia bands composed of grass ornamented on one side with a floral
design in colors were held dutiable as plaits or straws composed of
palm leaf under paragraph 422. (Abstract 32949 (T. D. 33587).)

ACT OF 1913.

The only change made in 1913 was to class bleached hats with
trimmed hats and to reduce the duties on hats unbleached or un-
trimmed from 35 to 25 per cent ad valorem and on hats bleached or
trimmed from 50 to 40 per cent.

Silk hatbands were continued as headings in the paragraph (par. 1115)
with ribbons, bellings, headings, etc., of silk or silk velvet. The pro-
vision was also continued for untrimmed hat bodies of silk plush (par. 1116)
free list). Yarns, threads, or filaments of artificial or imitation straw,
hair are made dutiable in paragraph 1114 at 45 per cent ad valorem,
and articles or fabrics wholly or in chief value of artificial or imitation

horsehair or of yarns, threads, filaments, or fibers of artificial or imitation horsehair and india rubber at 60 per cent ad valorem.

Straw hats trimmed with silk artificial flowers and ornamental feathers are dutiable at 60 per cent ad valorem under paragraph 347 as articles composed in chief value of feathers or flowers and not under paragraph 335 which, in so far as it relates to straw hats, is framed to make the trimmed hat an entity for determining whether, when trimmed, it is still composed in chief value of the materials therein named. (Aitken *v.* U. S., 6 Ct. Cust. Appls. 232 (T. D. 35468), affirming Abstract 37197.)

Unblocked and untrimmed hats of thin narrow shavings of bamboo held dutiable as hats of chip, not blocked or trimmed under paragraph 335 and not as manufactures of wood under paragraph 176. (Isler *v.* U. S., 7 Ct. Cust. Appls. 178 (T. D. 36503), affirming Abstract 37056 (T. D. 25000)).

Untrimmed hats made from pieces of buckram so cut and shaped as to make the separate pieces suitable for use as crowns, sides, or brims of hats, and which, after being covered with straw, are then fastened or sewed together by hand or machine, the completed article deriving its shape or form during the process of uniting the separate pieces of buckram together and not by the process of blocking, are dutiable, being in chief value of straw, at 25 per cent ad valorem under paragraph 335 and not as blocked hats at 40 per cent ad valorem. (In re Gage, G. A. 7996 (T. D. 36849)).

Merchandise classified as artificial silk braids under paragraph 319 was found to be composed in chief value of straw and dutiable accordingly under paragraph 335. (In re Comey & Johnson Co., Abstract 37005.)

Hemp braids not bleached, colored, or stained held dutiable at 15 per cent ad valorem under paragraph 335. (In re American Shipping Co., Abstract 37909.)

Hats from Mexico held to be dutiable on the appraised value in default of proof to the contrary, it not being the function of the Board of General Appraisers to conduct the case and produce evidence as requested by the importer. (In re Wyman, Abstract 38135.)

Manila hemp braids, classified as bleached, were found not to be bleached, dyed, colored, or stained and were accordingly dutiable at 15 per cent instead of 20 per cent under paragraph 335. (In re Steeb, Abstract 39160.)

Panama hats, in the absence of proof whether or not they were blocked and trimmed, held to be dutiable as trimmed hats as classified under paragraph 335. The appraising officer was without the authority to amend his appraisement and reduce the value from $10 to the entered value of $6. (In re Evans, Abstract 39256.)

Straw hat linings made of cotton netting, paper, and satin were classified as linings in part of cotton net at 60 per cent ad valorem under paragraph 358. In default of proof as to the component material of chief value, the protest claiming the rate of 30 per cent ad valorem under paragraph 256 or 25 per cent under paragraph 332 was overruled. (In re Valentine Hat Co., Abstract 40477.)

So-called wood shaving cloth, classified as manufactures of cotton at 30 per cent ad valorem under paragraph 266, was declared to be properly classifiable as unbleached willow squares used for making

hats under paragraph 335, but as that claim was not made by the importer the protest was overruled. (In re American Import Co., Abstract 40785.)

Ornaments consisting of strands of natural straw twisted together loosely and looped and tied, used as centerpieces in the crowns of straw hats, forming the starting points, were held dutiable as manufactures of straw at 25 per cent ad valorem under paragraph 368 and not at 60 per cent as artificial leaves under paragraph 347. (In re Zimmermann Co., Abstract 40979; Abstracts 21933, 40699, and U. S. *v.* Dieckerhoff, 4 Ct. Cust. Appls. 384 (T. D. 33796), followed.)

(In United States *v.* Dieckerhoff, small pieces of wax in the shape and color of fruit or vegetables, with a loop of ribbon attached as a handle, forming a part of the equipment for sewing baskets, were held to be dutiable at 25 per cent as manufactures of wax under paragraph 462, act of 1909, and not at 60 per cent ad valorem as artificial fruits under paragraph 438.)

Braids in chief value of manila hemp were held dutiable at the appropriate rate of 15 or 20 per cent ad valorem under paragraph 335 and not at 60 per cent ad valorem as composed in chief value of artificial silk under paragraph 319 or 358. (In re Bertrose Co. et al., Abstracts 41345, 41541, 41663.)

Braids in chief value of straw, dyed, colored, or stained held dutiable at 20 per cent ad valorem under paragraph 335 and not at 60 per cent as of silk chief value under paragraph 358. (In re Judkins, Abstract 41545.)

Unblocked and untrimmed hats made of thin narrow shavings of bamboo are dutiable as hats of chip, not blocked or trimmed, under this paragraph, and not as manufactures of wood under paragraph 176. (Isler *v.* United States, 7 Ct. Cust. Appls. 178, of 1916, followed in Abstract 40385, of 1916.) *Straw hats* of "Alpine" shape, known as "bodies," which have been placed upon a zinc brim form and subjected to slight hydraulic pressure in order to bring their brims to the proper widths according to style and demand, but which must yet be subjected to a blocking process by which they are stiffened with suitable sizing and pressed into permanent shape and conventional sizes, are not blocked. (Donat *v.* United States, 9 Ct. Cust. Appls. 169, of 1919; followed in Abstract 43797.) *Untrimmed straw hats* which have derived their shape and style by knotting the straws together with thread over a form are not blocked hats within the meaning of the statute, the provision for blocked hats embracing only such hats or hat bodies as have been subjected to the blocking process by placing the hats or bodies on a block or form and then manipulating them so as to give them the required form and style. (G. A. 8279, T. D. 38092, of 1919.) *Untrimmed hats made from pieces of buckram* so cut and shaped as to make the separate pieces suitable for use as crowns, sides, or brims of hats and afterwards covered with straw, then fastened or sewed together by hand or machine, the completed article deriving its shape or form during these processes and not by a process of blocking, are not dutiable as blocked hats, but as hats not blocked, under this paragraph. (G. A. 7996, T. D. 36849, of 1916, followed in Abstract 40870, of 1917, and G. A. 8161, T. D. 37607, of 1918.) *Untrimmed straw hats* with high crowns and wide brims so limp and pliable that they

do not retain any particular shape were held not to be blocked. Although made over a block to give the necessary size to the crowns, they had to be put through a further process of blocking in order to give them size and shape. (Abstract 40006, of 1916.) *Unblocked and untrimmed hats made of manila hemp, braids, cords, rings, and threads* into a finished article of coarse open work having the appearance of Renaissance lace are dutiable under the provision of this paragraph for "hats * * * composed wholly or in chief value of * * * manila hemp," that provision being more specific than the provision in paragraph 358 for "wearing apparel * * * made wholly or in part of lace or of imitation lace of any kind * * * of whatever yarns, threads, or filaments composed." (G. A. 8098, T. D. 37358, of 1917.) *Trimmed straw hats* with the trimming composed of silk, artificial flowers, and ornamented feathers, the two latter elements predominating, were held dutiable under paragraph 347 rather than under this paragraph, the trimmings controlling the classification. This paragraph, in so far as it relates to straw hats, makes a trimmed hat an entity for determining whether it, when trimmed, is still composed in chief value of the materials therein named. (Artken *v.* United States, 6 Ct. Cust. Appls. 232, of 1916.) So-called "*wood shaving cloth*" was found to be *bleached willow squares* used for making hats and dutiable under this paragraph rather than as manufactures of cotton under paragraph 266. (Abstract 40785, of 1917.) *Hemp chenille*, made by twisting two threads of cotton together and intertwining crosswise threads of hemp, used in the manufacture of hat braids, was held dutiable under paragraph 284 rather than this paragraph. (Abstract 43241, of 1919, followed in Abstract 43439, which was affirmed in T. D. 38372, of 1920; followed in Abstracts 43831 and 43862, of 1920.)

There are different rates of duty on hat braids that are bleached and those that are not bleached or dyed, but the rate is the same on hats dyed or bleached wholly or in part and hats not dyed. The rates are also the same on hats that are partially blocked and those that are not.

PREFACE.

s is one of a series of Tariff Information Surveys prepared by nited States Tariff Commission and transmitted to the Com- e on Ways and Means. The series covers all of the articles ommodities provided for in the tariff act of October 3, 1913, thers not specifically provided for. It is arranged in the rical order of paragraphs of that act.

some cases two or more paragraphs have been combined in amphlet. In doing this, industrial relationship of the articles een followed when possible. In those instances where a para- has been treated under a preceding paragraph of the tariff eference is made to this fact at the point where the paragraph urs in numerical order. Where one grade of an article is dutiable nother grade of the same article is on the free list, the article scussed under the dutiable paragraph, which appears first in rical order in the tariff act. In certain instances articles of industrial relationship and which occur in separate paragraphs e tariff act have been combined under one paragraph for con- nce of discussion. Reference is made to this fact at the point e the commodities would naturally occur in numerical order.

e first pamphlet in the series is an "Introduction and Index," n contains:

An introductory chapter discussing the scope of the series and eneral method of treatment.

An alphabetical index of the articles provided for in the tariff f 1913, showing the paragraph of the act in which the article ovided for and, if discussed under a different paragraph, the ber of such paragraph.

A list of the pamphlets in the series, showing the paragraphs articles included in each pamphlet.

us by use of this "Introduction and Index," the exact location ie discussion relating to a given article or commodity can be tained.

---

the preparation of this report the Tariff Commission had the ces of Guy G. George, of the Commission's staff, with relation ads, and of S. L. Willis, of the Metals Division of the Commis- s staff, with relation to jewelry and precious stones, and of rs.

BEADS, JEWELRY, AND PRECIOUS STONES.

BEADS AND SPANGLES.

SUMMARY.

ads, spangles, and ornaments, as well as other articles composed
ly or in part of beads and spangles, are included in one para-
ı, acts of 1894, 1897, 1909, and 1913. Since 1894 there has been
at increase in the variety of beads and spangles imported and
ange of prices has been greatly extended. It is contended that
articles should now be reclassified for tariff purposes. Small
" beads and cheap toy necklaces, for example, should not be
ed as manufactures of beads. Some think that loosely strung
s without a clasp are not finished articles and should not be
ired to pay duty as such; that imported beads of all kinds and
tones should be admitted at a low rate of duty, to enable domestic
lry manufacturers to compete with foreign establishments in the
stic market. The domestic production for most of the articles
ot sufficient to satisfy requirements under normal conditions.
foreign products appear, as a rule, to be of better workmanship
more desirable than the domestic.
ıt little machinery is used in the manufacture, and foreign estab-
ıents have the advantage of cheap labor. Nearly 70 per cent
e imports in 1918 came from France. Since 1914 there has been
increase in the domestic manufacture.

GENERAL INFORMATION.

1913 TARIFF PARAGRAPH.

ıR. 333. "Beads and spangles of all kinds, including imitation
l beads, not threaded or strung, or strung loosely on thread for
ity in transportation only, 35 per centum ad valorem; curtains,
other articles, not embroidered nor appliqued and not specially
ided for in this section, composed wholly or in chief value of
ls or spangles made of glass or paste, gelatin, metal, or other
erial, 50 per centum ad valorem."

DESCRIPTION.

he latest definition of "bead" in litigation is "a little perforated
re, ball, cylinder or the like, usually strung on a thread or attached
fabric for decoration." (G. A. 8356, T. D. 38452.)
spangle is a small plate or bar of shining metal or other material
l as an ornament, especially when stitched on the dress.
rtificial pearls are manufactured in a variety of ways. Some are
es of thin opaline glass, filled with gum or wax, and deadened

on the surface by means of hydrofluoric acid. The better kinds are glass globules lined with a nacreous composition formed by digesting the silvery scales of the bleak (a fish) in ammonia. Roman pearls are glass spheres, to which the nacreous material is applied externally. Celluloid, incorporated with fish scales, has become a favorite material for artificial pearls. Black pearls have been imitated by beads of a very compact plumbago luster. Pink pearls are frequently confounded with beads or pale coral.[1]

Materials.—As indicated by the list of the different kinds of beads, pearls, etc., various materials are used, but glass and metals predominate.

Methods of production.—Of the products covered by paragraph 333, artificial pearls are in most popular demand. They are manufactured by coating the interior of hollow glass beads with essence d'Orient; coating a solid glass bead with the same material and coating metal beads with a celluloid varnish. The hollow glass beads are sometimes filled with wax. Spangles are made of gelatine, metal, or other material, which is cut into small disks and then colored.

Most of the articles are made largely by hand, very little machinery being used. Since the decrease in imports, due to the war, a new process has been patented which enables the use of machinery in the manufacture of beads, and has apparently cheapened the price of the artificial pearls.

It is contended by the domestic producers that cheaper labor enables the foreign manufacturers to compete successfully in the domestic market, especially in the production of glass beads. Difference in the price of materials does not appear to be an important factor in foreign competition.

Domestic production.—There are no statistics of domestic production. The manufacture of glass, metal, and composition beads is largely an adjunct of other industries and the data for them have never been separated. The Federal census of 1914 gives separate totals for 19 establishments engaged primarily in "beadwork," i. e., the manufacture of bead and glass necklaces, beaded bags, collars, lamp shades, and novelties. The products for the year were valued at $1,083,000. The industry is largely concentrated in New York City. Since 1914 there has been an increase in the production of some varieties of beads especially wood, celluloid, vegetable ivory, and glass. The domestic production, however, is very small as compared with the imports and by no means satisfies the demand. The demand depends largely on fashion, especially for the glass ornaments.

Domestic exports.—Very few, if any, of the articles covered by paragraph 333 are exported.

Foreign production.—The industry, especially the manufacture of glass beads (imitation pearls), has been long established in France, Germany, Austria, Italy, and Japan, but there are no reliable statistics of the quantity or value of the annual production in any of these countries.

Imports.—The statistics of imports for consumption are shown separately for "beads and spangles," and "curtains and other articles not specially provided for of beads and spangles." The general imports, by countries are shown under "beads and bead ornaments."

[1] Dictionary of Applied Chemistry, Thorpe.

lue increased up to and including 1914 when it amounted to 941. Since then there has been a decrease and in 1918 they ted to $1,728,337, of which $1,208,567 came from France. 9, calendar year, the imports increased to $6,330,909, and for o $12,544,581. This appears to confirm the opinion of manu- rs and importers that imports would increase with the resump- normal conditions.

domestic manufacturers are not equipped to produce suffi- o meet normal requirements, and the foreign establishments to have the advantage both in the cost of production and ality of the products.

petitive conditions.—The manufacture requires a great deal dwork, and this is the principal reason why it has not devel- n the United States. It is the consensus of opinion that present industrial conditions the domestic manufacturers t compete successfully with the foreign establishments. The ry in foreign countries, especially in Italy, Germany, Austria, rance has the advantage of an old organization. Some of the ses are carried on in the homes of the operators and the work sed on to succeeding generations. Since 1914 machinery has sed to some extent in the United States, and will possibly en- he domestic manufacturer to compete in some lines.

Provided, That no article composed wholly or in chief value of beads or spangles made of glass, paste, gelatin, metal, or other material shall pay duty at a less rate than is imposed in any paragraph of this section upon such articles without such beads or spangles.	Do.
333	* * * curtains, and other articles not embroidered nor appliques and not specially provided for in this section, composed wholly or in chief value of beads or spangles made of glass or paste, gelatin, metal, or other material.	50 per cent.

COURT AND TREASURY DECISIONS.

'tains composed in chief value of glass or rice paste beads, strung
;ton threads suspended from a horizontal bar or rod, are dutiable
urtains * * * composed wholly or in chief value of beads"
this paragraph. The language "curtains, and other articles,
nbroidered nor appliquéd" in this paragraph does not exclude
rticles as are not susceptible of being embroidered or appliquéd.
ed States *v.* Morimura, 7 Ct. Cust. Appls., 285, of 1916.) Curtains
b's-tear seeds are dutiable by similitude to curtains of beads
this paragraph. (T. D. 36656, of 1916.) Artificial flowers,
, and stems made of beads with the aid of wires and silk thread,
g the size, form, color, and outline of natural flowers, are dutiable
paragraph 347 as "artificial and ornamental * * * leaves,
rs, and stems, or parts thereof, of whatever material composed,"
r than as beaded articles under this paragraph. (United States
erican Bead Co., 9 Ct. Cust. Appls., 27, of 1918.) Ornaments and
ings consisting of beads on a net foundation, beads chief value,
ore specifically provided for under this paragraph as articles
ppliquéd, composed wholly or in chief value of beads, than under
raph 358 as ornaments or trimmings of whatever yarns, threads,
aments composed. An article is appliquéd within the tariff
when it is ornamented with a pattern or design independently
ated. (Loewenthal *v.* United States, 6 Ct. Cust. Appls., 209,
13.) Silk netting ornamented with beads and spangles, the
g being more valuable than either and less valuable than both,
iable as "composed wholly or in chief value of beads or spangles"
this paragraph and not as "trimmings * * * of what-
yarns, threads, or filaments composed" under paragraph 358.
ed States *v.* Gavin, 7 Ct. Cust. Appls., 292, of 1916.) Necklaces
or without base metal clasps, in chief value of beads, the beads
made of wood, gelatin, or paste and china or colored glass,

some in imitation of jet and amber, are dutiable as articles in chief value of beads under this paragraph and not as jewelry under paragraph 356. (American Bead Co. *v.* United States, 7 Ct. Cust. Appls., 18, of 1916.) Necklaces substantially of imitation jet beads with imitation jet pendants are not dutiable as jewelry under paragraph 356, but as beaded articles under this paragraph. (Wolff & Co. *v.* United States, 7 Ct. Cust. Appls., 156, of 1916.) Beaded necklaces are not necessarily jewelry, and articles of personal adornment only are not necessarily jewelry. The jewelry paragraph 448 of the tariff act of 1909 embraced imitation amber; the jewelry paragraph, 356 in the tariff act of 1913 does not. (American Bead Co. *v.* United States, 7 Ct. Cust. Appls., 161, of 1916.) Necklaces in chief value of paste beads are not dutiable as jewelry under paragraph 356, but as manufactures in chief value of paste beads under this paragraph. (Bloomingdale *v.* United States, 8 Ct. Cust. Appls., 314, of 1918.) Imitation pearl beads strung temporarily upon flimsy cotton strings selected and graded as to size so that the beads graduate from the largest in the center to the smallest at either end, are dutiable as "imitation pearl beads * * * strung loosely on thread for facility in transportation only" and not as articles of beads under this paragraph. However useful for trade purposes may be the selecting and grading, the fact remains that the stringing was done for facility in transportation only, as the beads have to be restrung more durably and fitted with clasps before being practical for use as chains or necklaces. (Lorsch *v.* United States, 8 Ct. Cust. Appls., 246, of 1918.)

Beads loosely strung without clasps were held to come within paragraph 333 of the act of 1913. (Abstract 43740.) Necklaces made of wax filled glass imitation pearl beads, permanently strung and fitted with metal clasps and imitation pearl pendants, are classable as jewelry under paragraph 356 and not as articles or beads under paragraph 333. (United States *v.* Woolworth Co., 10 Ct. Cust. Appls.,—; T. D. 38552.) Glass bead girdles valued at more than 20 cents per dozen pieces were held to come within paragraph 333 and not to be dutiable as jewelry. (G. A. 8319, T. D. 38269, of 1920.) Chains, bracelets, hatpins, and necklaces composed in chief value of beads were held to come within paragraph 333. (Abstract 43629.) The following articles were also held under recent decisions to come within paragraph 333: Wooden bead necklaces (Abstract 43758); bone bead necklaces (Abstract 43901); necklaces composed of metal and beads, beads chief value (Abstract 43925); beads of paste composition permanently strung, but without clasps on the string and in appearance simulating a pearl necklace (Abstract 43926); trimmings or ornaments composed of beads, raffia, and cotton, beads chief value (Abstract 43838). But agate rings, $\frac{3}{8}$ of an inch in outside diameter and $\frac{1}{8}$ of an inch in thickness, the opening in each ring being a little more than $\frac{3}{16}$ of an inch in diameter, used as line-guides on fishing rods, were held not to be beads and to be duitable as manufacturers of agate within paragraph 98 of the act of 1913. "Beads" was defined as a little perforated sphere, ball, cylinder, or the like, usually strung on a thread or attached to a fabric for decoration. (G. A. 8356, T. D. 38452.)

Rosaries in chief value of beads were held dutiable as articles made of beads under paragraph 333. (United States *v.* American Express, 8 Ct. Cust. Appls., 157, of 1917.) Coral beads graduated and tem-

ily strung loosely on strings for facility in transportation, suit-
for use in the manufacture of jewelry, are not dutiable as beads
·ticles in chief value of beads under this paragraph, but as
al * * * cut, but not set, and suitable for use in the manu-
re of jewelry," under paragraph 357. (United States *v.* Barti-
9 Ct. Cust. Appls., 180, of 1919.) Coral beads which have been
o final globular shape, pierced, graded, and temporarily strung
.al relation from large to small for use and wear as coral necklaces,
similarly classified. (United States *v.* Bartimoro, 9 Ct. Cust.
s., 183, of 1919.) Christmas tree ornaments consisting of a star
sed in a circle 3 inches in diameter, composed of colored and
red or gilded glass perforated articles strung on metal wires
ng a pendant composed of similar glass articles strung on red
)n strings, and other articles of similar description, were held
·erly classified as beaded articles under this paragraph rather than
ufactures of blown glass under paragraph 84. (Abstract 42364,
)18.) (See pars. 167, 356, 359, and 358.)

1ere has been some uncertainty in the interpretation of the tariff
s for beads and spangles. If they are strung loosely for facility
·ansportation only, the rate is 35 per cent ad valorem, whereas
ıey are strung ready for use, the rate is 60 per cent ad valorem.
often difficult to determine into which classification the product
. Frequently the strands are complete with the exception of the
p, yet pay the lower rate of duty.

rticles in chief value of beads embroidered or appliquéd come
ıin neither this paragraph nor paragraph 358, but under provisions
)rding to the component material of chief value, such as glass.
ission of the words "not embroidered nor appliquéd and" would
)lify administration.

he classification of necklaces has given rise to much litigation.
ı rule they are jewelry when imported strung with a clasp, but
·n made of imitation jet or amber, or of wood, gelatin, paste,
s, or china, whether with or without clasps, they have been held
to be jewelry. A valuable collection of matched pearls used
)ad before acceptance, and imported unstrung, was also held not
)e jewelry.

'he classification of rosaries is also difficult. Three provisions are
ıcipally involved, this paragraph, paragraph 167, and paragraph
. Rosaries having devotional use have been held not to come
ıin paragraph 356, and are dutiable according to the component
hief value. When having a simple metal crucifix, rosaries might
lutiable at 50 per cent under this paragraph, and when having an
)orate crucifix of base metal, at 20 per cent under paragraph 167.

JEWELRY AND RELATED ARTICLES AND PARTS THEREOF.

SUMMARY.

ewelry is the name given to a large class of articles designed to be
·n on the person for purposes of adornment. It is generally made
or in imitation of, the precious metals. A large number of
cles designed to be worn on or carried about the person are classi-
with jewelry in the tariff.

ewelry articles are luxuries and the domestic consumption fluctu-
s in a large measure with general industrial conditions.

The domestic jewelry industry is well organized and efficient, and during the period from 1910 to 1919 the domestic production was generally sufficient to satisfy the domestic market. At times imports exceeded exports but since 1911 exports have predominated. The domestic industry originally manufactured only the best grade of jewelry, depending for its success on the originality of the design used. In recent years the industry has expanded, and now manufactures of all but the cheapest grades, which prior to the war were imported in large amounts and since 1914 have practically disappeared from the domestic market.

The manufacturing process requires a large amount of hand work because the demand for any one article is so unstable that, except for certain stock articles, such as chains, rings, and pin shanks, it would not pay to design automatic machinery for its manufacture. The industry is carried on in small plants to a large extent.

Foreign production.—Germany and Austria, France and England are normally large producers of jewelry. The Central Powers were active competitors with the domestic industry in the United States markets, especially as regards the cheaper grades of jewelry. The French and English industries produce a high quality product. The war shut off the German and Austrian markets entirely and caused large reductions in the jewelry output in England and France.

Competitive conditions.—The domestic industry occupies a very favorable position as regards the manufacture of the high and medium grades of jewelry. Design plays an important part in the sale of this material and as domestic manufacturers change their patterns frequently they are able to hold the market in the face of cheaper foreign competition. The low price of the cheaper flashy jewelry prohibits the expenditure of large sums to jewelry designers. The goods are manufactured in large lots from stock patterns, usually imitations of popular designs of expensive jewelry. The European industry excels in the manufacture of goods of this character, their ability to imitate design, the lower wage scale, and the prevalence of home manufacturing units, combining to make the foreign goods formidable competitors of the domestic article.

Tariff considerations.—The domestic jewelry manufacturing industry is well established and capable of supplying the entire domestic demand for all classes of jewelry. The revenue feature of the tariff situation in this industry is important. The imposition of high duties on these luxury articles may fall wide of the mark if the duties be fixed at rates which eliminate the foreign product from the domestic market.

The very cheap grades of foreign jewelry and novelties valued below the present limits of the jewelry paragraph (20 cents per dozen pieces) are luxuries, since they are used for adornment, and for this reason might be classified with the more expensive grades.

Jewelry and similar articles and parts thereof—Summary table (values).

iscal year.	Domestic production.	Imports for consumption.[1]	Domestic exports.[2]	Ratio of imports to exports.	Amount of duty.[1]	Average equivalent ad valorem rate.

GENERAL INFORMATION.

TARIFF ACT OF 1913.

Paragraph 356. "Jewelry, commonly or commercially so known, valued above 20 cents per dozen pieces, 60 per cent ad valorem; rope, curb, cable, and fancy patterns of chain not exceeding one-half inch in diameter, width, or thickness, valued above 30 cents per yard; and articles valued above 20 cents per dozen pieces designed to be worn on apparel or carried on or about or attached to the person, such as and including buckles, card cases, chains, cigar cases, cigar cutters, cigar holders, cigarette cases, cigarette holders, coin holders, collar, cuff, and dress buttons, combs, match boxes, mesh bags, and purses, millinery, military, and hair ornaments, pins, powder cases, stamp cases, vanity cases, and like articles; all the foregoing and parts thereof, finished or partly finished, composed of metal, whether or not enameled, washed, covered, or plated, including rolled gold plate, and whether or not set with precious or semiprecious stones, pearls, cameos, coral, or amber, or with imitation precious stones or imitation pearls, 60 per cent ad valorem. Stampings, galleries, mesh, and other materials of metal, whether or not set with glass or paste, finished or partly finished, separate on in strips or sheets, suitable for use in the manufacture of any of the foregoing articles in this paragraph, 50 per cent ad valorem."

Paragraph 167. "Articles or wares not specially provided for in this section: if composed wholly or in part of platinum, gold, or silver, and articles or wares plated with gold or silver, and whether partly or wholly manufactured, 50 per cent ad valorem * * *."

DESCRIPTION.

The jewelry manufacturing industry in the United States produces a wide range of articles, used for adornment or as novelties to be carried on or about the person.

The products of the jewelry industry may be roughly divided into four classes, depending on the raw material used: (1) Wire goods, such as pins, brooches, and rings; (2) chain and mesh goods, such as fancy chains for pendants and watch chains, and mesh bags used for ornamental handbags. These are produced from wire but are more highly manufactured than are the articles in division (1); (3) cast goods, including certain kinds of rings and intricate gem mountings; (4) stamped sheet metal goods used for ornamenting toilet articles and fancy bags, and for match boxes, cigarette and cigar cases, studs, buttons, cuff and collar links, and similar articles. The only specified articles which may require definition are "galleries," which are metal settings for precious stones, and "mesh," a fabric composed of small rings of wire linked together.

In general, any metallic article designed to be worn on the person for the purpose of adornment, whether or not it has a utilitarian use, is known as jewelry.

DOMESTIC PRODUCTION.

The domestic jewelry and novelty manufacturing industry is well established and capable of supplying the entire domestic demand.

Materials.—Ingots of gold, silver, platinum, brass and copper, and ets, strips, and wire composed of or plated with those metals are base from which almost all jewelry is made. Precious, semipre- us, and imitation precious stones are used for ornamentation. tain souvenir jewelry and novelty articles are composed in part shells, horn, ivory, wood, and other materials.

Equipment.—The manufacture of jewelry requires a large amount handwork. All stamped goods are made on hand-operated wer machines, but all dies used are manufactured by highly illed hand labor. All cast material is necessarily made in indi- dual molds, but the polishing of rough castings is usually carried n in power-operated drums. A large amount of the wire and mesh oods are made with automatic machinery, but the finishing is largely andwork.

Methods of production.—The jewelry industry is wholly dependent ıpon the vagaries of fashion, and for this reason, in order to keep ıbreast of competition, designs must be changed frequently. There s, therefore, little advantage in spending large amounts of money to make any one of the manufacturing processes automatic when the article made would be obsolete and have no market in a comparatively short time. Some articles, notably wire rings from which mesh material is made, finger rings manufactured from wire, shanks for stick pins, and certain kinds of gold and silver safety pins, have a sufficiently stable market to be made in large quantities, and automatic machines have been designed for their manufacture. Recently automatic mesh fabricating machinery has been perfected.

In 1914 the domestic industry provided work for 28,289 wage earners, of whom approximately three-quarters were male and one-quarter female. About 650 children of both sexes were employed. The domestic industry is carried on almost exclusively in factories, whereas in Europe large quantities of jewelry are manufactured in the homes of the workers. The large amount of handwork required places producing nations with low wage scales in a very advantageous position.

Organization.—The jewelry industry is well adapted to small manufacturing establishments. The manufacturing processes which permit of large scale automatic operation (manufacture of pins, rings, and fancy chains) are carried on in large factories, but most of the industry is composed of small establishments employing a small number of employees. The census of 1914 gives to the average factory 18 to 19 wage earners. Over $72,000,000 were invested in the industry in 1914, scattered among 1,914 manufacturing establishments.

Geographical distribution.—The jewelry manufacturing industry is concentrated in three localities in the United States—in and about Attleboro, Mass.; Providence, R. I.; and Newark, N. J. The concerns operating in these groups are manufacturers exclusively, and do not enter the retail field. They manufacture stock patterns which enter into competition with foreign articles, and do little or no designing of individual pieces on order.

The jewelry selling industry is concentrated in the various centers of population throughout the United States. The selling concerns, although they are primarily retail organizations, manufacture large amounts of special pieces of jewelry on order from their own or from

customers' designs. The products made are composed of gold and platinum, and stock articles of either foreign or domestic origin can not compete to any extent, because the products are of unique design, and the demand can not be anticipated.

History of the industry.—The domestic manufacturing industry dates back about 50 years. At first the industry was conducted in shops using little or no power or machinery of any kind. During this period, the products were expensive and no standardization was attempted. As the industry became better established, under the high duties ruling during the period from 1890 to 1913, the industry expanded and the variety of the products was increased. It was during this period that the domestic industry first began to manufacture the cheaper, in part, flashy jewelry hitherto manufactured abroad exclusively. These products are now the backbone of the Massachusetts and Rhode Island industry. During the war, the domestic industry expanded further, to take over part of the business previously controlled by the foreign industry, and manufacturers report that during 1919 they were unable to supply the domestic demand.

Domestic production and consumption.—During 1914 the domestic jewelry industry manufactured products valued at over 81 millions of dollars. During the fiscal year 1914 the exports of jewelry and silverware combined exceeded the imports by $150,000, indicating a production in excess of the domestic consumption. Statistics for fiscal years 1910 and 1911 showed an excess of imports over exports. The situation was reversed in 1912 and exports have exceeded the imports during every year, except 1914, up to and including 1919. The war has been an important factor in the growth of domestic exports. German export trade was cut off in 1914, and in the Allied Nations the jewelry industry was forced to curtail operations. In the emergency, the neutral markets were supplied by the domestic jewelry industry.

Domestic exports.—Exports of jewelry have increased steadily since 1910. There was a period of stagnation during 1912 and again during 1915, but on the whole the recoveries were rapid. Exports average more than $1,500,000 per year and during the year 1917 amounted to $1,780,000 in value. Exports have decreased since 1917 due no doubt to the curtailment of domestic production when the United States entered the war. Prior to the war, Canada and South America were the heaviest buyers of domestic jewelry but considerable amounts were exported to France, Germany, and England.

FOREIGN PRODUCTION.

Germany, Austria-Hungary, France, England, and Switzerland are normally large producers of jewelry. The German and Austro-Hungarian industry, specializing in the cheapest grades, was the most active competitor in the domestic market. Imports from Germany and Austria-Hungary were greater than the imports of all other nations combined, averaging over $500,000 yearly and at times exceeding $1,000,000. Imports from France averaged about $400,000 per year and from England about $50,000. With the advent of the war, imports from the Central Powers decreased rapidly and ceased entirely in 1917. The Allied Nations continued to export jewelry

ɔughout the war years but in small amounts. Nineteen hundred
l nineteen figures show an increase over the last war year.
:he general trend of jewelry imports has been downward. The
ır 1914 (fiscal), the only normal year since the duty on novelty
ɨicles was lowered from 85 to 60 per cent, showed an increase of
9,000 over 1913, but during the period 1910 to 1913 imports
ɔcreased from $1,576,000 to $988,000. During the late war years,
ıportations decreased to less than $300,000.

TARIFF HISTORY.

The general tendency of tariff legislation regarding jewelry has ɔeen to increase the duties and to include in the jewelry provision the articles akin to, but not known as, jewelry.

The duties increased from 25 per cent ad valorem in 1883 to 60 per cent on true jewelry and to 85 per cent on novelty articles in 1909. In the tariff act passed in the latter year all articles designed to be worn on or carried about the person, similar to jewelry, were included in the jewelry paragraph but carried duties of 85 per cent, whereas articles known as jewelry were dutiable at 60 per cent. There was considerable litigation due to the involved wording of the paragraph.

The tariff act of 1913 clarified the situation somewhat. The paragraph was made to include all articles known as jewelry when valued at more than 20 cents per dozen pieces, all fancy patterns of chain when valued at above 30 cents per yard, and all the enumerated articles when valued at more than 20 cents per dozen pieces. No limitation was placed on the materials entering into the composition of the articles treated. A duty of 60 per cent was placed upon the finished or partly finished articles, and 50 per cent upon materials such as stampings, galleries and mesh used in their manufacture.

In the act of 1913 it was recognized that practically all articles, except scientific apparatus, composed of gold, silver, or platinum, or plated with those metals, are akin to jewelry. The general basket metal paragraph was divided and a duty of 50 per cent placed upon the manufactures of the precious metals.

COMPETITIVE CONDITIONS.

The domestic jewelry manufacturing industry depends for success, to a considerable extent, upon its ability to create new styles and designs before cheap foreign counterparts of existing designs lower the demand for the domestic product. A wide variety of articles must be manufactured at all times, and with few exceptions the demand for any one class of article is very limited. Originally the domestic industry catered exclusively to the high class trade. The product was in competition with the foreign articles, but in general was composed of more expensive metal, was of more original design, and commanded a higher price. As the industry became better established the variety of articles produced increased to cover certain of the cheaper articles formerly manufactured exclusively abroad. These articles are largely of standardized designs, and the larger volume of sales justify the installation of automatic machinery. The domestic industry manufacturing cheap jewelry, sacrificed the advantage of original design, but has been successful in holding a substantial part of the domestic market.

No attempt was made during the war to manufacture the cheapest grades of jewelry and novelties. As a result, this material disappeared from the market.

TARIFF CONSIDERATIONS.

All articles covered in this survey are in the luxury class. The domestic industry is firmly established. Therefore in determining the tariff treatment to be accorded articles, such as jewelry, which are manufactured in large amounts in the United States, it is to be noted that a high duty may easily result in decreased revenue through the exclusion of the foreign articles.

The cheap articles, at present below the value limit of the jewelry paragraph (20 cents per dozen pieces), should be classed as articles of adornment. The foreign industry is in a better competitive position as regards this class of material because the consumption is heavy, and the value of the finished article is so low that individual design plays little part in the competitive position of the article.

Jewelry and related articles and parts thereof—Rates of duty.

Act of—	Par.	Tariff classification or description.	Rates of duty, specific and ad valorem.
1883	459	Jewelry of all kinds	25 per cent ad valorem.
1890	452	Jewelry: All articles, not elsewhere specially provided for in this act, composed of precious metals or imitations thereof, whether set with coral, jet, or pearls, or with diamonds, rubies, cameos, or other precious stones, or imitations thereof, or otherwise, and which shall be known commercially as "jewelry," and cameos in frames.	50 per cent ad valorem.
1894	336	Jewelry: All articles, not specially provided for in this act, commercially known as "jewelry," and cameos in frames.	35 per cent ad valorem.
1897	434	Articles commonly known as jewelry, and parts thereof, finished or unfinished, not specially provided for in this act, including precious stones set, pearls set or strung, and cameos in frames.	60 per cent ad valorem.
1909	448	Chains, pins, collar, cuff, and dress buttons, charms, combs, millinery and military ornaments, together with all other articles of every description, finished or partly finished, if set with imitation precious stones composed of glass or paste (except imitation jet), or composed wholly or in chief value of silver, German silver, white metal, brass or gun metal, whether or not enameled, washed, covered, plated, or alloyed with gold, silver, or nickel, and designed to be worn on apparel or carried on or about or attached to the person, valued at 20 cents per dozen pieces, 1 cent each and in addition thereto three-fifths of 1 cent per dozen for each 1 cent the value exceeds 20 cents per dozen; all stampings and materials of metal (except iron or steel), or of metal set with glass or paste, finished or partly finished, suitable for use in the manufacture of any of the foregoing articles (except chain valued at less than 30 cents per yard other than nickel or nickel-plated chain), valued at 72 cents per gross, 3 cents per dozen pieces and in addition thereto one-half of 1 cent per gross for each 1 cent the value exceeds 72 cents per gross; rope, curb, cable, and other fancy patterns of chain, without bar, swivel, snap, or ring, composed of rolled gold plate or of silver, German silver, white metal, or brass, not exceeding one-half of one inch in diameter, breadth, or thickness, valued at 30 cents per yard, 6 cents per foot, and in addition thereto three-fifths of 1 cent per yard for each 1 cent the value exceeds 30 cents per yard; finished or unfinished bags, purses, and other articles, or parts thereof, made in chief value of metal mesh composed of silver, German silver, or white metal, valued at $2 per dozen pieces, 10 cents per piece and in addition thereto three-fifths of 1 cent per dozen pieces for each 1 cent the value exceeds $2 per dozen; all of the foregoing, whether known as jewelry or otherwise and whether or not denominatively or otherwise provided for in any other paragraph of this act, 25 per cent ad valorem in addition to the specific rate or rates of duty herein provided; all articles commonly or commercially known as jewelry, or parts thereof, finished or unfinished, including chain, mesh and mesh bags and purses composed of gold or platinum, whether set or not set with diamonds, pearls, cameos, coral, or other precious or semiprecious stones, or imitations thereof.	Do.
1913	356	Jewelry, commonly or commercially so known, valued above 20 cents per dozen pieces, 60 per cent ad valorem: rope, curb, cable, and fancy patterns of chain not exceeding one-half inch in diameter, width, or thickness, valued above 30 cents per yard; and articles valued above 20 cents per dozen pieces designed to be worn on apparel or carried on or about or attached to the person, such as and including buckles, cardcases, chains, cigar cases, cigar cutters, cigar holders, cigarette cases, cigarette holders, coin holders, collar, cuff, and dress buttons, combs, match boxes, mesh bags, and purses, millinery, military, and hair ornaments, pins, powder cases, stamp cases, vanity cases, and like articles; all the foregoing and parts thereof, finished or partly finished, composed of metal, whether or not enameled, washed, covered, or plated, including rolled gold plate, and whether or not set with precious or semiprecious stones, pearls, cameos, coral, or amber, or with imitation precious stones or imitation pearls.	Do.
		Stampings, galleries, mesh and other materials of metal, whether or not set with glass or paste, finished or partly finished, separate or in strips or sheets, suitable, for use in the manufacture of any of the foregoing articles in this paragraph.	50 per cent ad valorem.

COURT AND TREASURY DECISIONS.

What constitutes jewelry for tariff purposes has long been a troublesome question. The act of 1883 (par. 459) read "jewelry of all kinds." This was held to be governed by trade meaning. Proof of commercial designation was advantageous to the importer. In 1890 (par. 452) the provision read "all articles * * * which shall be known commercially as 'jewelry.'" The rate of duty was twice that of 1883, and it was to the advantage of importers to prove the articles were not commercially known as jewelry. In 1897 (par. 434) the word "commonly" was substituted for "commercially." Ordinary meaning was thus made the criterion, but commercial testimony was nevertheless still admitted and considered. In 1909 (par. 449) both terms "commonly" and "commercially" were used, with the disjunctive "or." Either trade or common meaning was accordingly sufficient for classification of articles as jewelry. "Commonly or commercially" was retained in 1913. Commercial usage is always a question of fact, to be established by evidence. Caprice of fashion or advantages of trade may vary it. (United States *v.* International Forwarding Co., 6 Ct. Cust. Appls., 25, of 1915; American Bead Co. *v.* United States, 7 Ct. Cust. Appls., 18, of 1916.) Common meaning, on the other hand, is matter of law within judicial knowledge. Testimony, however, as well as dictionaries and other authorities may aid the court. (American Bead Co. *v.* United States, 7 Ct. Cust. Appls., 18, of 1916.)

Without attempting a comprehensive definition, the Court of Customs Appeals has declared jewelry in common conception to be composed of precious metals or imitations thereof, or of precious or semiprecious stones, pearls or imitations thereof, or cameos, coral or amber, including artificial, synthetic or reconstructed pearls, rubies, or other precious stones strung or set. (American Bead Co. *v* United States, 7 Ct. Cust. Appls., 18, of 1916.) Jewelry may be useful as well as ornamental; all articles of personal adornment are not jewelry. (United States *v.* International Forwarding Co., 6 Ct. Cust. Appls., 25; United States *v.* American Express Co., 6 Ct. Cust. Appls., 97; United States *v.* Altman, 6 Ct. Cust. Appls., 131, of 1915; American Bead Co. *v.* United States, 7 Ct. Cust. Appls., 18, of 1916; Bloomingdale Bros. et al. *v.* United States, 8 Ct. Cust. Appls., 314, of 1918.)

Jude pendants suitable for necklaces, but completely finished, were held not dutiable as jewelry by reason of the fact that there was no metal work in their composition. (G. A. 8390. T. D. 38543 of 1920.)

Ivory, wood, and tortoise-shell bracelets were also held not to be dutiable as jewelry. (Abstract 44022 of 1920.)

"Designed" in "designed to be worn on apparel or carried on or about or attached to the person" refers to such articles as are specially fitted for being carried on or about the person and devoted to such use. (United States *v.* Faber, 7 Ct. Cust. Appls., 406, of 1917.) The controlling question, apart from value and material, is whether the articles are designed to be so worn, carried, or attached in the same manner as the enumerated articles and like articles when in their customary use. (Gallagher *v.* United States, 6 Ct. Cust. Appls., 105 of 1915.) Congress did not intend to include in the jewelry provision any such articles not composed of metal unless commonly or commercially known as jewelry. (American Bead Co. *v.* United

States, 7 Ct. Cust. Appls., 18, of 1916.) Bone watch charms were held to be manufactures of bone and not jewelry, articles of bone not being jewelry. (U. S. *v.* Mandel, 10 Ct. Cust. Appls., —, T. D. 38294.) Bone brooches (Abstract 43785) and pendants of bone (Abstract 43974 of 1920, holding also that pendants of ivory are dutiable as manufactures of ivory) were likewise classified. Articles of jet have likewise been held not to be jewelry. (U. S. *v.* Beierle, 1 Ct. Cust. Appls., 457; U. S. *v.* Sheldon & Co., 2 Ct. Cust. Appls., 283; American Bead Co. *v.* United States, 7 Ct. Cust. Appls., 18, T. D. 36259; Wolff & Co. *v.* United States, 7 Ct. Cust. Appls., 156; Abstracts 43804, 43806, and 43905 of 1920.) The words "like articles" following articles enumerated after the words just quoted must be ejusdem generis with the articles named. (Gallagher *v.* United States, 6 Ct. Cust. Appls., 105, of 1915.) Rosaries of silver-plated metal and colored glass, metal chief value, were held dutiable under paragraph 167. (United States *v.* American Bead Co., 7 Ct. Cust. Appls., 132, of 1916.) But silver-plated metal rosaries were classified under paragraph 356 at 60 per cent ad valorem. (Abstract 43785, of 1920.) Whether they are "designed to be worn on apparel or carried on or about or attached to the person" is a matter of evidence. (United States *v.* Malhami & Co., 7 Ct. Cust. Appls., 175, of 1916.)

Cigar lighters designed to be carried on the person being within paragraph 356 and also paragraph 381 as smokers' articles, was held by virtue of paragraph 386, dutiable under paragraph 356 of the act of 1913. (Bischoff & Co. *v.* United States, 7 Ct. Cust. Appls., 138. of 1916.)

Compasses of metal and glass were held to come within paragraph 356. (Abstract 43805, of 1920.)

The words "parts thereof" and "composed of metal" do not refer to jewelry. (Mamluck & Co. et al. *v.* United States, 6 Ct. Cust. Appls., 556, of 1916; American Bead Co. *v.* United States, 7 Ct. Cust. Appls., 18, of 1916.) An article not an actual constituent of a manufacture can not be considered as a part thereof unless it has been advanced to a point which definitely commits it to that specific class and kind of manufacture. (United States *v.* American Bead Co., 9 Ct. Cust. Appls., 27, of 1919.) Articles composed in chief value of metal with a substantial minor value of other material, the metal value distinctly preponderating, are within the phrase. (Hensel *v.* United States, 6 Ct. Cust. Appls., 162, of 1915.)

Hatpins with large paste heads of a pearly luster and metal gold-plated shafts, paste chief value, were held dutiable under paragraph 95 of the act of 1913 as manufactures of paste rather than under paragraph 167 as gold-plated articles or under paragraph 356 as jewelry. Paragraph 167 was restricted to articles or wares wholly or in chief value of metal. Every importation regardless of size, use, or shape, which remotely resembles a pearl in color can not be regarded as an imitation pearl and classified as jewelry. (Veith *v.* United States, 10 Ct. Cust. Appls., —; T. D. 38554.)

The words "separate or in strips or sheets" following "stampings, galleries, mesh and other materials of metal," are not words of limitation inserted to narrow the scope of the sentence, but words of amplification to make certain that whether imported in the form of strips or sheets or as separate entireties cut therefrom, stampings, galleries,

mesh and other materials of metal, capable of such forms should not escape the duty prescribed by the provision. (French Import Co. *v.* United States, 7 Ct. Cust. Appls., 460, of 1917.) "Suitable for use" does not imply or require chief use, but susceptibility for the use expressed. (United States *v.* Lorsch & Co., 8 Ct. Cust. Appls., 109, of 1917.)

Metal vanity cases are dutiable at 60 per cent under this paragraph but leather vanity cases, even though the contents be of metal and metal chief value of the entirety, are dutiable at 35 per cent under paragraph 360. Some parts of vanity cases are dutiable under paragraph 356 of the act of 1913 at 60 per cent, but small mirrors suitable for use in fitting out vanity cases are dutiable at 30 per cent under paragraph 95.

Necklaces, as a rule, are jewelry and dutiable at 60 per cent under paragraph 356, but necklaces of various materials, such as imitation jet, are not so classified. (United States *v.* Beierle, 1 Ct. Cust. Appls., 457, of 1911; American Bead Co. *v.* United States, 7 Ct. Cust. Appls., 18; Wolff & Co. *v.* United States, 7 Ct. Cust. Appls., 156; American Bead Co. *v.* United States, 7 Ct. Cust. Appls., 161, of 1916.)

But necklaces made of wax-filled glass imitation pearl beads, permanently strung and fitted with metal clasps and imitation pearl pendants were classified as jewelry under paragraph 356 of the act of 1913, and not under paragraph, 333 as articles of beads. The provision in paragraph 356 for such jewelry as is valued above 20 cents per dozen pieces was declared to indicate that in the congressional view there is cheaper jewelry and serves to show that whether or not merchandise is to be classified as jewelry is not to be determined by its value. (United States *v.* Woolworth Co., 10 Ct. Cust. Appls., —; T. D. 38552.)

PRECIOUS STONES AND PEARLS, NOT ADVANCED IN VALUE FROM THE ORIGINAL STATE.[1]

SUMMARY.

Precious stones are crystals of various rare minerals. They are cut to enhance their beauty and then set in jewelry. The diamond, a crystalline form of carbon, is the most important stone, the production surpassing in value that of all other gems combined. Some precious stones, notably the diamond, are used in the trades for cutting glass, engraving on copper, as dies for wire drawing, as an abrasive for truing emery wheels, and for bearings in delicate machinery. The United States possesses no large developed economic deposits of precious stones. The domestic production varies widely from year to year but seldom amounts to over $300,000.[2] This figure is almost insignificant in comparison with the imports.

Pearls are of organic origin, and occur as secretions in several species of shellfish. Most of the world's production of pearls are

[1] See also surveys on cut gems, and imitation pearls and precious stones.
[2] Domestic production is gems other than diamonds, and in this branch of the industry domestic production plays an important part.

found in the sea oysters native to the South Pacific Ocean, but the production from the fresh-water clams of the Mississippi River and its tributaries amounts to about $300,000 annually.

Imports of pearls and precious stones fluctuate with general industrial conditions. Large increases are noted during prosperous years, the importations decreasing materially during periods of financial unrest. During the period 1910 to 1919, inclusive, the maximum imports of precious stones and pearls was in 1919, when about $51,000,000 worth were entered. The minimum imports were about $14,000,000 in 1915.

Most of the precious stones imported have been cut abroad and are imported as finished gems, but of late years the domestic gem-cutting industry has expanded materially, and during 1918 importations of rough stones amounted to almost 47 per cent of the total importations.

TARIFF CONSIDERATIONS.

Precious stones suitable for use as gems are used for no other purpose. The stones used for industrial purposes are those unsuitable for gems because of defects. Bort is the general term used to denote diamonds and parts of diamonds which are unsuitable for gem use. Miners', glaziers', and engravers' diamonds are subdivisions of this class of material. At present miners', glaziers', and engravers' diamonds are admitted free, and unclassified material is dutiable at 10 per cent.

Gems are so easily concealed about the person that any increase of duty above a nominal percentage results in extensive smuggling operations. It is difficult to smuggle unset stones because, aside from the fact that the values per unit of weight is much less than that of cut stones, the cutting industry is concentrated in and around New York City, and all sales of stones are easily traced. Cut stones, on the other hand, may be disposed of to retail jewelers throughout the country.

General Information.

PAR. 357, TARIFF ACT OF 1913.

Diamonds and other precious stones, rough or uncut, and not advanced in condition or value from their natural state by cleaving, splitting, cutting, or other process, whether in their natural state or broken, and bort; any of the foregoing not set, * * * , 10 per cent ad valorem; pearls, and parts thereof, drilled or undrilled but not set or strung, * * *, 20 per cent ad valorem.

PAR. 474. Glaziers' and engravers' diamonds, unset, miners' diamonds. Free.

PAR. 520. Jet, unmanufactured. Free.

PAR. 463. Coral, marine, uncut, and unmanufactured. Free.

PAR. 390. Agates, unmanufactured. Free.

DESCRIPTION AND USES.

Precious stones are crystals of various rare minerals which are used in jewelry, after cutting and polishing to develop the color and refraction. Precious stones are sold by weight. The unit, called a "carat" (caret), is equal to 205 milligrams or $\frac{1}{151}$ part of an ounce troy.

The diamond, a crystalline form of carbon, is the most important gem stone. It is usually transparent, is the hardest known substance, and possesses a very high index of refraction so that when cut it sparkles under the light. Diamonds are either colorless, yellow, bluish, pink, or black. The bluish white stones are most prized, and are worth more per carat than the pink, yellow, or black crystals. The diamond has always been a fashionable stone and for this reason the price has increased in the face of greatly increased production. Recently, very small artificial diamonds have been produced, but so far all attempts to produce stones suitable for gems have resulted in failure. The value of the world's diamond production is greater than that of all other precious stones combined.

Bort is diamond material not suitable for use as gems.

Emerald is a deep green variety of beryl, and *ruby* is a deep red variety of corundum (aluminum oxide). Both stones are produced in very limited quantities from scattered deposits, and fine specimens command higher prices than diamonds of the same size.

Sapphire is a white, yellow, or blue variety of corundum. The blue stones are the most valuable, but the yellow and white stones are used extensively as cheap gems.

Tourmalines are anhydrous aluminum-boron silicates. The crystals are red, pink, green, or black. The value depends on the color and the freedom from flaws.

Garnets are iron-aluminum or magnesium-aluminum silicates. The crystals are deep red in color. The stone is rather common and the value is small.

Turquoise is a blue opaque mineral composed of phosphate of alumina, colored with a little iron and copper.

Beryl is a beryllium-aluminum silicate. The color may be white, yellow, pink, blue, or green. The deep green phase is the emerald, the blue is called aquamarine, and the yellow, golden beryl.

Silica, the oxide of silicon, is a gem mineral of great importance. The milky white transluscent form is the opal. Chalcedony, agates, and petrified wood are dense noncrystalline forms of the same mineral. The crystallized forms are known as rock crystal, amethyst, and other names depending on the color.

Pearls are of animal origin. They are formed by several species of shellfish—notably the oyster, salt-water mussel, and fresh-water clam—as a secretion about any grit that finds its way between the shells and can not be expelled. They possess a high polish when found and do not require further treatment to fit them for use as gems. They are, therefore, in the same class as cut diamonds, although no additional work has been performed upon them.

Coral is the shell of certain marine crustacea.

Jet is a hard pitch-black coal, capable of taking a high polish.

Agate is a variety of quartz which is peculiar in consisting of bands or layers of blended colors. Certain varieties are distinguished, as ribbon agate, fortification agate, moss agate, star agate, zone agate, clouded agate, etc. Most commercial agate is artificially stained, so that stones naturally unattractive come to be valuable for ornamental purposes.

Many other stones are used as gems, but to a limited extent only. A complete list of gem minerals—numbering many hundreds—is to be found in Mineral Resources of the United States, 1917, Part II.

USES.

Precious stones are used as gems, and some, notably the diamond, have been turned to limited commercial use.

The black form of diamond is widely used as the cutting agent in the diamond rock drill, and chips from the gem diamond are used for cutting glass and engraving on copper and steel. Diamond dust is used as an abrasive for cutting and polishing diamonds and other gems. Inferior diamonds are used for truing abrasive wheels. The automobile industry is a large consumer. Drilled gem diamonds are used as dies for drawing very fine wires.

Small rubies, sapphires, and other precious stones are used as bearings in watches and other delicate mechanisms.

Agates are used in rings, cups, beads, handles of small utensils, burnishers, pestles, mortars, and trivial ornaments, and in delicate mechanisms, such as bearing-surface pivots and knife edges of weighing apparatus.

SUBSTITUTES.

In general, it may be said that semiprecious stones are used as imitations of precious stones. Cheap imitations of every known precious stone are made of glass. The ruby and sapphire are the only stones that have been produced artificially of a size suitable for gems. Artificial rubies and sapphires of large size and fine color have been produced, which can be distinguished from natural stones only with extreme difficulty. Mined rubies of good color are worth up to $1,000 per caret but synthetic stones may be bought for $10 to $20 per carat.

DOMESTIC PRODUCTION.

Precious stones are widely distributed over the earth but no extensive deposits of any of the major precious stones have been developed in the United States. The only precious stones that have been produced commercially in this country are the sapphire, turquoise, tourmaline, garnet, topaz, beryl, and several varieties of quartz. Domestic production of several of these varieties is often sufficient to supply the domestic demand.

Diamond.—Occasional diamonds have been found in the glacial drift in Michigan, Wisconsin, and Illinois, and in placer deposits in North Carolina, but all attempts to discover the source of the supply have failed. A rock formation in Arkansas, similar to the "pipes" of so-called "blue ground" from which the bulk of the South African production is produced, is now being developed. More than a thousand diamonds, some of considerable value, were found during previous development work at this deposit and it is possible that deposits of large extent and great value will be discovered as the present development proceeds.

Sapphires are found in considerable quantities in several localities in Montana, but in general the deposits are scattered and do not justify commercial development. One dike deposit containing sapphires is known and has been worked to some extent. The rough stones are exported and are cut abroad.

Turquoise.—A large quantity of turquoise and turquoise matrix material is produced from widely scattered veins in Arizona and New Mezico, and southern California.

Garnets are produced in North Carolina, but only in small quantities. Imperfect crystals suitable for abrasive purposes are abundant and are mined extensively.

Topaz has been found in the Thomas Mountains, Utah, and in San Diego County, Calif.

Beryl.—Pink and blue-green beryl or aquamarine have been found in California.

Tourmalines are found in granitic dikes in Maine, California, and Connecticut. The gems occur in pockets and are recovered as a by-product of the quarrying operation.

Quartz is one of the most widely distributed rock minerals, but large crystals of colors suitable for gems are rather rare. The blue variety known as amethyst, the colorless form known as rock crystal,

and the dense noncrystalline variety known as chalcedony, agate, or petrified wood have been found here in some quantity.

Numerous localities yield agates. They are abundant in trap rocks of the Lake Superior region. Wood agate, or agatized wood, is found in Colorado, California, and elsewhere in the West, the famous "silicified forest" known as Chalcedony Park, in Arizona, being most noted. Foreign agates are found mainly in Uruguay and Brazil; these were formerly sent to Germany where their polishing was an important industry.

Pearls are produced in the United States in some quantity. The river clams, caught in the Mississippi River for their shells, are an important source of supply. Occasional gems are found in the thin-shelled mussels, native to the ponds and streams of eastern United States, and in the common edible oyster.

Organization.—Most, if not all, of the precious-stone production of the United States, with the exception of the production of a few small turquoise mines in the Southwest, are from small pockets. Little capital is employed in the mining industry.

Domestic consumption.—The United States is the largest consumer of precious stones in the world. The imports of diamonds alone amount to between 30 and 35 million dollars yearly, and compared to this figure the domestic production is insignificant.

Domestic exports.—Nil.

FOREIGN PRODUCTION.

The commercial deposits of precious stones are widely scattered; emeralds are mined extensively in Colombia, South America; sapphires and several related minerals, in Siam and Ceylon; garnets, in Bohemia; topaz, in the Ural Mountains of Russia and in Brazil; turquoise, in Persia; beryl, in Madagascar; and opals, in New South Wales, Hungary, and Mexico. A large part of the gem pearl supply is found in an oyster native to the islands of Oceania. Coral is imported from Italy.

Diamonds were formerly obtained from the alluvial deposits of India, and later from extensive deposits in Brazil. The chief supply of black diamonds for use in diamond drills comes from the latter locality.

In recent years the Kimberly mines of South Africa have supplied over 95 per cent of the total diamond output of the world. In South Africa diamonds occur in a peculiar serpentine breccia known as "blue ground." This material fills what appears to be the necks of extinct volcanoes. After weathering on the surface for some time, the diamond-bearing material is broken up and the diamonds recovered by passing the gravel over greased shaking tables. The diamonds stick to the greased surface and are recovered.

The entire South African diamond supply, except for that from a few minor placer producers, is controlled by one large syndicate that regulates the sale and distribution of the product. In this way the production is controlled, the market is stabilized, and violent fluctuations of price are prevented. The entire production was shipped to England before the war and then distributed to the various cutting centers, such as Amsterdam, Brussels, Antwerp, and Paris. New York City has become an important cutting center in recent years. During the war considerable quantities of placer stones were shipped direct to New York from South Africa.

IMPORTS.

Imports of precious stones vary directly with the prosperity of the country. In unsettled periods as during the fiscal year 1915, the imports are comparatively small while in prosperous periods, when the general buying power is increased, the imports of gems are greatly stimulated. During the 10-year period, 1910 to 1919, inclusive, the value of imports of diamonds and other precious stones, including pearls, fluctuated from $14,555,224 in 1915 to $48,210,381 in 1913.

In 1910 only 22 per cent of the total value of precious stones (chiefly diamonds) imported were rough or uncut but the percentage of uncut stones has increased steadily and in 1918 amounted to 48 per cent of the total imports.

TARIFF HISTORY.

Pearls were dutiable at 10 per cent ad valorem in every tariff act from 1883 to 1909, inclusive. In 1913 the duty was increased to 20 per cent ad valorem.

In the act of 1883, diamonds, rough or uncut, were admitted free, but other precious stones either rough or cut, were dutiable at 10 per cent ad valorem. All precious stones, uncut, were admitted free under the tariff of 1890, but a 10 per cent duty was imposed in the act of 1894. All uncut precious stones were admitted free under the tariff acts of 1897 and 1909. In 1913, uncut precious stones of all kinds were made dutiable at 10 per cent ad valorem.

Diamonds destined for commercial use in the industries, including glaziers', engravers', and miners' diamonds, and diamond fragments not suitable for gems (bort), were on the free list in the tariff acts of 1883, 1890, 1894, 1897, and 1909. In the tariff act of 1913, bort, n. s. p. f., was made dutiable at 10 per cent ad valorem, but miners', glaziers', and engravers' diamonds remained on the free list.

COMPETITIVE CONDITIONS.

As there is no stable precious stone producing industry in the United States, the prices charged for diamonds in the United States are based on the syndicate price, the price charged by the De Beers (English) producers, plus duty. The value of uncut stones is something of a gamble; the syndicate compels the buyer to accept the seller's assortment, and, furthermore, small flaws and variations of color can not be seen in the rough stone. There are two factors which tend to increase the cost of a cut stone above the theoretical cost obtained by adding the cost of cutting to the price of the rough stone. In the first place it is necessary to cut away a large and variable part of the original stone in cutting, and finally a charge must be made for the stones which on cutting prove to be of poor grade, and for those which are broken in the process.

TARIFF CONSIDERATIONS.

Precious stones, suitable for use as gems, are used for no other purpose. They are therefore luxuries. The rate of duty has very little effect on the amount of stones imported, but high duties always place a premium on smuggling, and as diamonds, especially, represent a large amount of money in small space, a fortune in the stones can be hidden about the person.

The smuggler buys his stones in the European market and as he pays no duty he has a 20 per cent advantage in the United States market in competition with honest imports and 10 per cent advantage in competion with domestic cutters who were obliged to pay 10 per cent duty on their raw material. A decreased duty on uncut stones decreases the smugglers' advantage over the domestic cutter but does not alter his advantage over the importer of cut stones.

A large supply of smuggled cut stones demoralizes the domestic cutting industry as well as the legitimate importing of cut stones, especially when, as at present, the rough material is dutiable. The American Jewelers' Protective Association assert that a large amount of semiprecious stones was formerly imported rough on approval. The duty on uncut stones makes this procedure difficult of operation and handicaps the domestic cutter in purchasing his raw material. They estimate that doubling the duty causes four times as much smuggling, and the result may easily be a reduction in the revenues, not to mention the damage done the domestic cutters and honest importers due to the large quantities of smuggled stones entering the market in competition with the legitimate importations.

Bort is the name given to a large class of diamonds which are not suitable for use as gems. It includes the black diamonds, or carbonado, used in diamond drills (miners' diamonds), diamonds showing irregular crystal structure which will not polish, irregular fragments of gem diamonds obtained in the cutting process and used in glass cutting and engravers' tools (glaziers' and engravers' diamonds), diamonds which have been drilled for use as dies in wire drawing machines, diamonds suitable for use in dressing abrasive wheels, and other diamond fragments of no particular industrial use. Under the present classification, fragments which are suitable for use in miners' drills and glaziers'and engravers' tools are admitted free (par. 474), although the unmanufactured fragments are dutiable. (Par. 357.)

There is little temptation to smuggle uncut stones because they must be marketed through a diamond-cutting establishment. As the industry is concentrated around New York, all sales are easily traced. Cut stones, on the other hand, may be sold to any one of the thousands of retail jewelers throughout the United States without exciting suspicion.

Under the present classification matched pearls, which, when strung, form a necklace, are admitted at 20 per cent if imported unstrung. Matched and graded pearls are worth more than individual pearls of the same size and the value is the same either strung or loose.[1] The duty on a strung necklace, however, is 60 per cent, since it is an article commonly known as jewelry.

Value per unit of weight regardless of the mineral composition appears to be the only effective basis of distinction between precious and semiprecious stones. Rarity, color, and size are factors in determining the value of gem minerals, and fashion may raise a comparatively common stone to the rank of precious gem. Sapphires are found in several colors—from white through yellow and blue to red—and the value may vary from a few dollars to a thousand

[1] There was testimony in case U. S. r. Citroen that pearls graded for a necklace are less valuable than the aggregate values of the individual pearls, but the evidence was contradictory, other witnesses testifying that pearls were worth more as a necklace. It is probable that the auction value of the necklace is less than that of individual pearls, but when the pearls have been accumulated on order from a prospective buyer conditions are reversed.

dollars a carat. The value of diamonds depends largely on color; brown stones are comparatively inexpensive, while blue-white and the fancy-colored gems are probably the most valuable known. The value of Chinese jade while usually much less than that of diamonds varies between wide limits, the value being based upon color and to a certain extent upon age. Amethyst and aquamarines are popular at present and the value in consequence is considerably higher than it had been for some years. Other stones formerly ranking with the more valuable gems have lost caste because of changed preference or increased production.

Value of precious stones produced in the United States in 1918, by States.

1913	390	Agates, unmanufactured	Do.

COURT AND TREASURY DECISIONS.

The court can not disregard the condition upon which the law makes the duty depend. Temporary stringing for facility in transportation only precludes classification as "not threaded or strung." (Frankenberg Co. *v.* United States, 206 U. S. 224, of 1907.) Under the rule that dutiable classification must be ascertained upon examination of the article in the condition in which it is imported, pearls ready for stringing and actually strung as a necklace before importation were held not pearls set or strung for tariff purposes, but "pearls in their natural state, not strung or set" (par. 436, act of 1897). The court also held that a prescribed rate of duty can not be escaped by disguise or artifice; but if an article imported is not the article described as dutiable at a specified rate it does not become dutiable under the description because it has been manufactured for the purpose of being imported at a lower rate. (United States *v.* Citroen, 223 U. S., 407, of 1912.)

Separate provision is made in the act of 1913 for beads, including imitation pearl beads, temporarily strung for facility in transportation only (par. 333), but none for pearls.

See Surveys on Precious Stones Advanced and on Imitation Precious Stones.

PRECIOUS AND SEMIPRECIOUS STONES, ADVANCED.

(See also U. S. T. C. Surveys on Uncut Precious Stones and Imitation Precious Stones.)

SUMMARY.

Description and uses.—Cut precious stones are crystals of various minerals which have been shaped or cut, and polished, to enhance their color and brilliancy. Diamonds, rubies, emeralds, sapphires, and opals are the most important and valuable of the precious stones, but many other minerals are used as gems, although the market in most cases is limited. Precious stones are used for ornamenting jewelry and novelty articles. The diamond is by far the most important precious stone and data contained in this survey applies to diamonds except where otherwise stated.

Domestic production.—The domestic production of gem minerals is small, but the domestic industry engaged in cutting gems of foreign origin, is well organized, and during 1919 (fiscal year) fully one-third of the gem imports were rough crystals which were cut in the United States. The manufacturing process is largely handwork, and the skill of the operator plays a large part in the successful operation of the industry. Fifty-eight to sixty-one per cent of the rough stone is lost in the cutting operation, but the waste is marketable for industrial and abrasive purposes.

The diamond cutting industry is carried on principally in and about New York City, and is conducted in both small and large shops. Expert diamond cutters command salaries of over $100 per week.

Foreign production.—Amsterdam and Antwerp have always been the world's largest precious stone cutting centers. In Europe, the industry is carried on in both large and small shops, and in many cases the workers are confined to members of the cutter's family.

The war eliminated Belgium and greatly curtailed the industry in Holland because of the scarcity of raw material. As diamond production was resumed in South Africa, the Dutch, French, English, and especially the United States cutting industry expanded to supply the demand formerly satisfied by the Belgians. The Belgian industry is now operating again. The English cutting industry profited by the war and Great Britain is taking steps to retain the advantage gained.

Imports.—Imports of gems fluctuate with the prosperity of the country. There has been a general increase in the value of rough material. In 1910 importations of rough stones were 22.8 per cent of the total, and in 1919 33.5 per cent. Imports of cut stones during 1914, 1918, and 1919 were valued at approximately $20,000,000, $8,700,000, and $69,000,000, respectively.

Prices.—The value of a gem varies with the variety, size, cutting, color, and the freedom from flaws.

Tariff history.—High duties on precious stones result in extensive smuggling operations, and for this reason the duties on gems have always been held at a comparatively low level. In the act of 1894 finished gems were dutiable at 25 per cent, and at present they are dutiable at 20 per cent, but in the other acts since 1883 a uniform rate of 10 per cent was maintained. Rough stones were on the free list in the tariff acts of 1883, 1890, 1897, and 1909. In the acts of 1894 and 1913 they were made dutiable at 10 per cent.

Competitive conditions.—The domestic cutter competes actively and successfully with the European under present conditions, at least on material legitimately imported, but the European cutter is able to work up smaller stones and chips, thus obtaining larger profit from his waste material. The cutting of chips and very small stones is, in some cases, performed by women or by apprentices in the trade.

That part of the industry working on precious stones other than diamonds is highly organized abroad, but the domestic industry can compete in this field under normal conditions. Total importations of cut stones during the period 1910–1919 were valued at twenty times the value of rough stones imported, but rough material of this character is quite inexpensive, and domestic production is considerable.

Tariff considerations.—The more precious gems (diamonds, emeralds, natural rubies, natural blue sapphires, opals, and pearls) are very valuable per unit of size or weight and are easily concealed about the person. A high duty encourages smuggling and in the end demoralizes the market by discouraging legitimate importations. In the last year of the period 1894 to 1897, when duties were 25 per cent on cut stones and 10 per cent on rough material, the revenue from gem duties was less than that during the fiscal year 1894, when the duty was 10 per cent.

All branches of the gem and jewelry industry (cutters, importers, wholesalers, and retailers) are united in favor of a tariff of not over 10 per cent on the most precious cut stones.

It would appear that higher duties on precious stones other than diamonds, blue sapphires, rubies, emeralds, opals, and pearls would not result in excessive smuggling, but as the imports are largely individual stones of great beauty the value per carat often places them in the same class with diamonds. Furthermore higher duties on these so-called semiprecious stones would seriously affect the export market for the fine jewelry in which these stones are mounted.

GENERAL INFORMATION.

ɔ also T. I. C. surveys of uncut precious stones and imitation ıus stones.)

TARIF ACT OF 1913.

'. 357. * * *; diamonds, coral, rubies, cameos, and other ıus stones and semiprecious stones, cut but not set, and suitable ıe in the manufacture of jewelry, 20 per cent ad valorem.

DESCRIPTION AND USES.

t precious and semiprecious stones are crystals of various min- which have been cut and polished to enhance their color and ıncy. Rubies and diamonds are true precious stones. Coral is nell of a marine crustacea. Cameos are precious stones (usually) which have been carved in relief. The Italian cameos con- f a light and a dark layer of mineral. This is carved so that one forms the relief carving and the other the background.
t gems are used for ornamentation on jewelry and expensive lty articles. Precious stones which are to be used for industrial ɔses are manufactured by rough shaping; these products are ed in the survey on uncut precious stones.

DOMESTIC PRODUCTION.

ıe crude, rough crystals of mineral used for gems are found in all ɜ of the world, as described in the survey on uncut precious stones. rough stones are sent to cutting centers and very few, if any, are ıt the point of origin.
aterials.—Rough crystals of the gem mineral are used as raw ɔrial. Lead or cement is used to hold the crystal during the ng and polishing operation, and diamond dust or other abrasive ed for shaping the stone.
quipment.—Very simple machines are used for grinding and pol- g the faces of the crystal. Handwork is the most important of the procedure, and the cutter's success depends on his obtain- he maximum possible weight of cut gem from his raw material. crystals are sawed by a disk of metal impregnated with diamond

ethods of manufacture.—Rough diamond crystals are first care- inspected for flaws and irregularities and then split along the ral cleavage planes. In this operation it is often possible to inate flaws so that perfect cut stones can be produced from ɔd, rough material. The divisions formed by the first splits are ɔrked up into gems if of sufficient size. The later splits and d fragments produce slivers of crystal that are used for glaziers' engravers' diamonds or are ground to powder for abrasive pur- ɜ.
ıe roughly shaped gem is imbedded in a cake of lead or cement roughly shaped by grinding it against another diamond. The ɜs are cut by pressing the stone against a revolving table covered diamond dust and oil. The stone must be reset for grinding quarter and the cutter is the sole judge of the amount of grind-

ing necessary. In a trade of this kind where a slight error of judgment may spoil a stone worth thousands of dollars, skilled labor commands a high price and wages run over a hundred dollars a week. A perfectly cut stone contains 64 facets besides the table.

Emeralds, rubies, and other precious stones are cut in various shapes to bring out the color and brilliance. They are softer material, and are more easily shaped. Carborundum dust is used instead of diamond dust for cutting and the facets are polished with tripoli powder.

A skillful cutter will produce cut diamonds weighing from 39 to 42 per cent of the weight of the rough crystal. The shape of the raw material and the prevalence of imperfections plays a large part in the possible recovery and cut stones weighing as little as 30 per cent and as much as 50 per cent of the weight of the rough stone are by no means uncommon.

Organization.—The diamond and precious-stone cutting industry is operated in both large and small units. Most of the rough diamonds are bought from the British diamond syndicate, and for this reason there is eager competition for places on the mailing list of that organization. The syndicate offers the stones in assortments at a fixed price and the cutters are forced to accept the syndicate valuation sight unseen or lose their place on the list. Large quantities of diamonds are sold rough by the original purchasers, but this source of supply is uncertain.

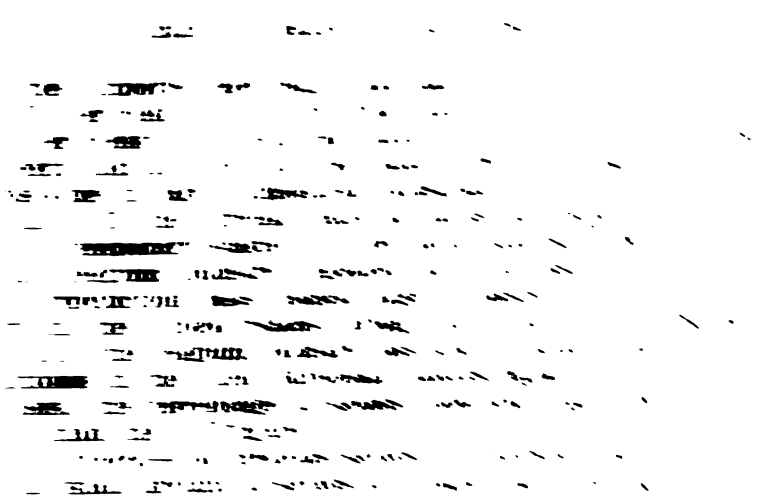
Geographical distribution.—The precious-stone cutting establishments are concentrated in and about New York City. A few cutting establishments are located in other districts, but the total weight of diamonds cut outside is small. The shops outside the New York district specialize on semiprecious stones.

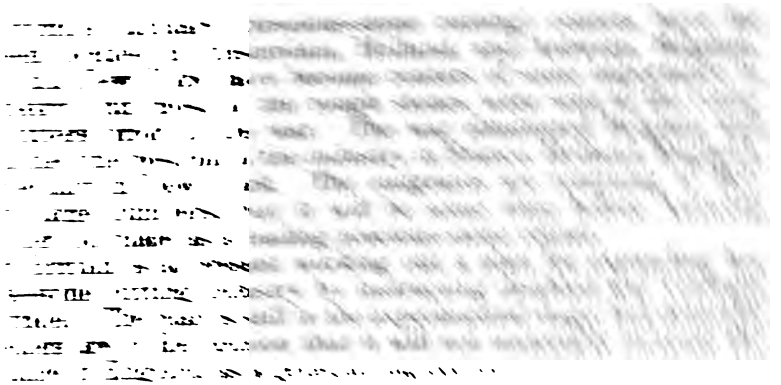
History of the industry.—Precious stones were practically all cut abroad until about 1875. The expanding market for cut stones (especially diamonds) in the United States and the 10 per cent domestic duty on cut stones caused Belgium and Dutch cutters to locate in New York. The large jewelry houses installed cutting establishments to handle their special trade, and the cutters, recruited abroad, often opened shops of their own after a period of employment with the store that brought them to this country.

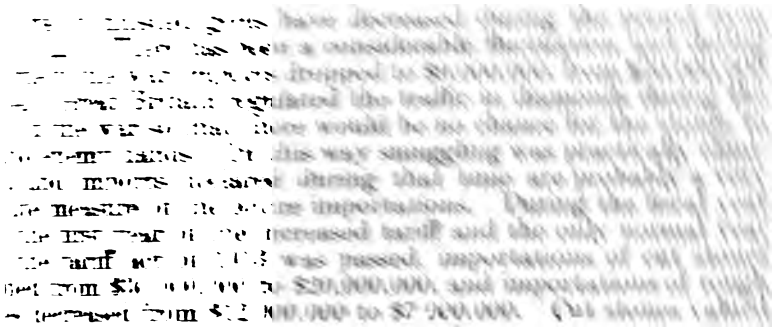
The industry suffered a reverse in 1896–97, but since that time has grown steadily. At present fully a third of all the precious stones sold in the United States are cut in New York.

At the outbreak of the war large numbers of the Belgian cutters migrated to Holland, England, and to the United States. This has resulted in a surplus of labor in the New York market, but the condition is temporary, as most of the Belgian refugees are returning to Belgium.

Domestic production and consumption.—Although the United States absorbs more diamonds than any other nation, the domestic production of gem material is very small. The domestic cutting industry, on the other hand, has increased steadily, and New York is fast becoming one of the world's great precious-stone cutting centers. There are no data available by which the number of carats of cut stones produced here can be determined, but import valuations of rough and cut material show the ratio between the values of the imports of each kind. In 1910 (fiscal year), 22.8 per cent of the







Total importation of cut and rough stones in fiscal year 1894 (low tariff) were $4,900,000, and in 1897 were only $2,200,000. During the 3-year period importations of cut stones decreased steadily. There was a temporary increase in the importations of rough stones, but in 1897 importations decreased rapidly and duties collected were less than in 1894.

After the passage of the act of 1897 reducing the duty on cut stones to 10 per cent and restoring rough material to the free list, imports increased to almost $6,900,000 per annum, and duties collected were greater by $20,000 than in 1897. Part of the violent fluctuations during the period were due to unsettled industrial conditions, but smuggling was the chief influence at work. During the period 1883 to 1894 gem importations averaged over $10,000,000 per year.

PRICES.

No standard prices on diamonds and other precious stones are recognized in the trade. Small stones possessing no distinctive features are standardized to some extent, but in dealing with the larger stones, color, freedom from flaws, shape, and other factors enter into the determination of value.

In general the value of a dimaond is greatest when the stone is white or has a blue tint, is free from flaws, and perfectly cut. Matched stones are more valuable than single stones of the same size.

TARIFF HISTORY.

Because of the fact that gems are easily concealed, and therefore may be smuggled with great ease, the duties on gems have always been comparatively low, although they are purely luxury articles. The duty on cut stones was 25 per cent under the act of 1894 and is 20 per cent at present, but under the acts of 1883, 1890, 1897, and 1909 the duty was only 10 per cent.

Rough stones are dutiable at 10 per cent under the act of 1913. In 1894 the duty on crude stones was the same as at present, but in every other act since 1883 this material was on the free list.

COMPETITIVE CONDITIONS.

The skill of the worker is an important factor in the competitive position of the gem-cutting industry. A cutter recovering 40 per cent of his raw material as finished gems has a better chance than one saving only 35 per cent, and in many cases the extra weight saved will go far toward paying the cost of cutting. In Europe the industry is carried on in both large and small units; in fact, a large part of the business is carried on in the home of the cutter and at leased benches in large shops. The man of the house does all splitting and grinding on the larger stones, while apprentices work up the smaller gems produced by the splitting operation. This method of conducting the industry, together with the lower scale of living, enables the foreign workers to cut smaller and less valuable stones than can be profitably handled in the United States. Wages in Amsterdam in 1920 are about 45 per cent of those paid in the United States.

e of great value and are easily concealed about the person. ent great possibilities to the professional and amateur and in any discussion of the tariff situation it is well to the effect of extensive smuggling on the legitimate im- on the revenue accruing to the Government.

ically, an increase in the duty rate would result in increased but in practice, if the increased rate is above a low percent- continued over a period of years the opposite occurs. Gem timate that smuggling increases faster than the duty. That ing the duty causes four times the smuggling that occurs wer rate. The smuggler is able to undersell legitimate im- and the amount of legitimate importations decrease because rter no longer has a stable market. As the legitimate stocks , the demand for smuggled goods increases and is followed by r increase in the amount smuggled. This movement may e so marked as to reduce the revenue to a point below that l under the lower rate. The effect, furthermore, is to demor- e market and to foster friction with the Government among iest importers who feel that they are entitled to protection the smuggled goods. The domestic cutter is in little better n than is the importer of cut stones unless the uncut material ie free list. The smuggler has an advantage, then, if manufac- costs abroad are lower than in the United States. Any duty rough stones operates as a direct handicap to the cutter.

ail sales of gems abroad are easily traced, and for this reason erage citizen buying precious stones for his own use has small e of evading the duty. The professional smuggler, however, nis stones from the cutter; the sales are seldom if ever reported, he customs officials have no advance warning. Unless the gler is known, the chance of his being apprehended is very [1]

e precious stone and jewelry industry is unanimously in favor w duties, preferably not over 10 per cent on cut stones. Cutters, rters, wholesalers, and retailers, all agree that higher duties result tually in low revenue returns to the Government and a disor- zed domestic industry.

iamonds, natural rubies, emeralds, natural blue sapphires, pearls, possibly opals, are the only stones which ordinarily are valuable ugh to pay the smuggler for the risk he runs. The other stones y be made dutiable at a rate comparable to that levied on other ely luxury articles without endangering the domestic market or reasing the revenues accruing to the Government. The European ters dominate the semiprecious stone industry under present con- ions and imports of cut stones other than diamonds average over ,000,000 as compared with about $100,000 imported in the rough ate.

Against this reasoning it must be said that higher duties on semi- ecious stones would seriously affect the export market for fine welry in which these stones are set.

[1] Interviews with trade (corroborate), Tariff Hearings on this subject.

Dealers assert that imports of cut stones other than diamonds consist largely of the more precious stones as named above, together with other gems which because of their great beauty or individual characteristics may be placed in the same class.

In order to encourage the gem cutting industry in South Africa, the Government of that colony does not collect the 10 per cent duty, ordinarily levied on exports of diamonds, if the material is exported as cut gems. This provision gives the South African cutter a 10 per cent advantage over the European cutter, and a 20 per cent advantage over cutters located in the United States, when competing in the European market.

480	Precious stones of all kinds.....	10 per cent ad valorem.
454	Precious stones of all kinds, cut but not set.....	Do.
338	Precious stones of all kinds, cut but not set, * * *	25 per cent ad valorem; * * *
	Imitations of precious stones, not exceeding an inch in dimensions, not set.	10 per cent ad valorem.
435	Diamonds and other precious stones advanced in condition or value from their natural state by cleaving, splitting, cutting, or other process, and not set.	Do.
	Imitations of diamonds or other precious stones, composed of glass or paste, not exceeding an inch in dimensions, not engraved, painted, or otherwise ornamented or decorated, and not mounted or set.	20 per cent ad valorem.
449	Pearls and parts therof, drilled or undrilled, but not set or strung	10 per cent ad valorem.
	Diamonds, coral, rubies, cameos, and other precious stones and semiprecious stones, cut but not set, and suitable for use in the manufacture of jewelry.	Do.
	Imitation precious stones, including pearls and parts thereof, for use in the manufacture of jewelry, doublets, artificial, or so-called synthetic or reconstructed pearls and parts thereof, rubies, or other precious stones.	20 per cent ad valorem.
357	Diamonds and other precious stones, rough or uncut, and not advanced in condition or value from their natural state by cleaving, splitting, cutting, or other process, whether in their natural form or broken, and bort; any of the foregoing not set, and diamond dust.	10 per cent ad valorem.
	Pearls and parts therof, drilled or undrilled, but not set or strung; diamonds, coral, rubies, cameos, and other precious stones and semiprecious stones, cut but not set, and suitable for use in the manufacture of jewelry.	20 per cent ad valorem.
	Imitation precious stones, including pearls and parts thereof, for use in the manufacture of jewelry, doublets, artificial, or so-called synthetic or reconstructed pearls and parts thereof, rubies, or other precious stones.	Do.
	Small pieces of jade cut into oval, round, diamond, and square shapes, and small pieces carved to imitate a dog or other small animal on a pedestal, the former set into rings and the latter used for watch charms, were also held dutiable at the 20 per cent rate under paragraph 357 of the act of 1913. (Abstract 38702, of 1915.)	

COURT AND TREASURY DECISIONS.

Precious and imitation precious stones may be imported in the mails. (T. D. 36718, of 1916; T. D. 37384, of 1917.) The court can not judicially know that opals described by the evidence, without samples, as having one surface cut and polished are "rough or uncut, and not advanced in condition or value from their natural state by cleaving, splitting, cutting, or other process." (Wells *v.* United States, 7 Ct. Cust. Appls., 346, of 1916.) Coral cut or made globular into a bead is "cut" within paragraph 357; and coral beads graded as to size and temporarily strung are "not set." The term "beads of all kinds" in paragraph 333 does not include any of that class of beads constituting jewelry or material for use in the making of jewelry. (United States *v.* Bartiroma, 9 Ct. Cust. Appls., 183, T. D. 38003, of 1919.) Reduction of a precious stone to the desired form and condition for use in the manufacture of jewelry is "cutting" within paragraph 357. (United States *v.* Battiloro, 9 Ct. Cust. Appls., 180, T. D. 38002.) Industrial diamonds (filieres diamant), drilled for use as wire drawing dies, come within paragraph 357 of the act of 1913 as "bort." (Abstract 42946, of 1919, T. D. 43545.) Rough uncut pieces of diamonds of a cheap variety which may be used for engraver's points or for diamond drills after the points are sharpened, commercially known as "bort," are also bort within paragraph 357 and not exempt from duty as engraver's diamonds under paragraph 474. (G. A. 7839, T. D. 36048, of 1916.)

Beads of precious or semiprecious stones are dutiable under paragraph 357 at a lower rate than paragraph 333 imposes on other beads.

Semiprecious stones are specified in connection with precious stones cut but not set, but not with precious stones rough or uncut.

Bort, a general name for industrial diamonds, is dutiable under paragraph 357, while glazier's, engraver's, and miner's diamonds are exempt from duty under paragraph 474. Diamond dust is for the same class.

(See list survey upon imitation precious stones and jewelry.)

The term "precious stones" was held to be a trade term which includes "not only the diamond, sapphire, emerald, pearl, opal, and turquoise, but also the garnet, beryl, topaz, rock crystal, lapis lazuli, agate, onyx, jade, amethyst, tiger-eye, chalcedony, bloodstone, moonstone, tourmaline, chrysoprase, etc." Small cups, shoe-hook and glove-hook handles, knife handles, paper weights, seals for mailing boxes and for blotting papers and similar articles made of agate or of onyx were held dutiable by similitude as precious stones being identical in material with well-known kinds of precious stones although advanced by their manufacture into specific commercial articles beyond the condition of precious stones. Hahn *v.* United States, 107 Fed., 95, following Erhardt *v.* Hahn, 57 Fed., 271, applying "precious stones" to the mineral substances and not to articles made therefrom. The Hahn case was further followed as to manufactures of jade, except that the articles were classified as articles composed of mineral substance. Tiffany *v.* United States, 120 Fed., 255.

es and tourmalines, being whole mineral substances family of precious stones of a like green color with ty of 3 to 3.25 and hardness of 7.5, are of the same emerald and other highly prized gems, and even if im- e rough are precious stones within paragraph 357 of 13. G. A. 8382, T. D. 38519.)

nder the act of 1913, small pieces of jade cut into oval, ond, and square shapes, and small pieces carved to g or other small animal on a pedestal, the former being s and the latter used for watch charms, were classified, d in the manufacture of jewelry, under paragraph 357, ler paragraph 98 as articles composed wholly or in chief niprecious stones. (Abstract 38702.)

intended for bearings for electrical instruments were le as precious stones under paragraph 435 of the act of than as articles composed of mineral substances under 97. (United States v. American Express Co., 147 Fed., small pieces of Ceylon sapphires in the form of rough ed V or cut jewelry and used as bearings for electric other electric measuring instruments were declared to be precious and not semiprecious stones and were held to under paragraph 95 of the act of 1909 as "articles com- arthy or mineral substances" and not within paragraph niprecious stones, cut but not set," by similitude. (United eneral Electric Co., 4 Ct. Cust. Appls., 287.)

d "set" as used in the provision in paragraph 435 of the 7 for "diamonds and other precious stones advanced in or value from their natural state by cleavings, splitting, other process, and not set," was declared to have a well- d well-defined trade meaning in connection with precious ich would not include an agate bearing in a scale, and the was held to be intended to cover only precious stones y purposes and to exclude such as were fitted for use as (Smith v. Computing Scale Co., 147 Fed., 890.) But pal balls about one-fourth of an inch in diameter and ock crystal rondelles, or small, flat faceted disks, were ome within the provision for precious stones in paragraph e act of 1897 rather than within the provision for "beads ds" in paragraph 408. (United States v. American Gem l Co., 142 Fed., 283.) Rock crystal intaglios, produced pensive manner by engraving, and then painted, were held under the act of 1897, paragraph 135, as precious stones l in condition or value * * * by * * * cutting process regardless of their advancement in value by paint- nited States v. Benedict, 145 Fed., 914.)

nit of weight for diamonds, pearls, and other precious stones etric carat of 200 milligrams. (T. D. 33562, of 1913.)

lso surveys on precious stones and pearls, not advanced, and n precious stones.)

IMITATION PRECIOUS STONES.

SUMMARY.

Very few imitation gems (precious stones and pearls) are manufactured in the United States. The bulk of the supply is imported from France, Switzerland, and Bohemia (Czechoslovakia), where the industry has been brought to an advanced state of perfection.

Imitation gems are used in the manufacture of jewelry and may be classified with parts of jewelry (par. 356). The value per unit is small and high duties are little or no incentive to smugglers.

(See Tariff Commission surveys on precious stones.)

GENERAL INFORMATION.

TARIFF ACT OF 1913.

Par. 357. Imitation precious stones, including pearls and parts thereof, for use in the manufacture of jewelry, doublets, artificial or so-called synthetic or reconstructed pearls and parts thereof, rubies or other precious stones, 20 per cent ad valorem.

DESCRIPTION AND USES.

Imitation precious stones are usually glass replicas of the more valuable precious stones. The skill of the ceramist has developed into an art in this branch of the industry and the stones produced can be distinguished from the genuine gems only after delicate tests of their hardness and index of refraction. Glass imitations are made of every known gem.

Synthetic or "reconstructed" stones differ from the imitation article in that they are of the same composition as the true gem and are frequently produced by melting powder from the gem mineral in an oxyhydrogen flame. Some specimens of synthetic rubies and sapphires resemble the mined gem so closely that experienced gem experts have great difficulty in distinguishing one from the other. Sapphires and rubies are the most important stones produced in this way.

Imitation pearls have been made for years from small glass globes coated on the inside with the microscopic scales of a European fish. These imitations are well made but can be detected easily. Recently other processes have been perfected which, the originators claim, duplicate the natural growth of the pearl in the oyster. These pearls are beautiful specimens and sell for good prices. They are more expensive to produce than the fish-scale varieties but are better imitations and their detection requires the services of an expert. The industry manufacturing this material is still in the experimental stage.

Imitation precious stones and pearls are used for decorating cheap jewelry and novelties.

DOMESTIC PRODUCTION.

The United States has never been an important producer of imitation precious stones, and the domestic production is small.

ears, however, domestic manufacturers have produced
quantities of imitation pearls, but no stable industry
veloped.

RAW MATERIALS.

he most important raw material used in the manufacture
precious stones. The variety of glass used contains a
ntage of lead which increases the index of refraction and
brilliancy of the stone. Very small percentages of other
and oxides are added to produce the color desired. In
acture of synthetic sapphires and rubies chemically pure
oxide is used together with a small amount of metal salt
ring agent. Dust and chips from cutting natural gems
be employed.

EQUIPMENT.

olds are used of about the size and shape of the finished
ne finishing is done on revolving tables covered with abra-
er. Hand work predominates but automatic machinery is
some varieties of imitation stones. The manufacture of
gems requires a delicate apparatus surrounding an oxy-
blow pipe.

METHODS OF MANUFACTURE.

nitations of precious stones are pressed in molds of the size
required in the finished stone. The facets are then ground
hed on a revolving table first with carborundum and finally
oli powder.

ed paste diamonds are composed of highly refractive glass
ay be covered with a layer of rock crystal to give a hard
surface. Rock crystal or clear quartz is an important
n the imitation-gem industry. It is used in the manufacture
ass, and the unaltered crystal, when cut and polished, is used
ely as a brilliant.

ion pearls have been produced in France for many years.
ass globes are coated on the inside with a solution of silvery
es in ammonia. The beads may be filled with wax or other
after coating to protect them from breakage. A process has
rfected recently for producing imitation pearls of the same
tion throughout. This product rivals the true pearl in luster
uty.

netic gems are produced by dropping fine aluminum oxide
through an oxy-hydrogen flame. The material is liquified in
and falls on a table a little below the zone of intense heat, but
ugh so that the melt solidifies very slowly and assumes the
ne form. The artificial crystal (called a "boule") is cut in
ne manner as the mined stones.

ORGANIZATION.

w of the better grades of imitation pearls are produced in the
States but otherwise domestic production of imitation gems
The stones are imported from Europe and distributed by New
mporters.

GEOGRAPHICAL DISTRIBUTION.

Most of the imitation precious stones used in the United States are imported through the port of New York. The only domestic manufacturers are located in New York City and Providence, R. I.

HISTORY OF THE INDUSTRY.

The use of glass for imitation precious stones was known to the ancient Romans. In recent years the industry has been carried to perfection in France, Switzerland and Bohemia. Domestic manufacturers have never been in a position to compete with the imported product.

DOMESTIC PRODUCTION AND CONSUMPTION.

The domestic production of imitation gems is negligible as compared with the imports. No production figures are available.

EXPORTS.

Exports are confined to stones of foreign origin contained in exports of domestic jewelry.

FOREIGN PRODUCTION.

France, Switzerland, and Bohemia (Czechoslovakia) produce the bulk of the imitation gems. The foreign products are noted for their brilliance and luster, and perfect workmanship.

IMPORTS.

Imports of imitation gems fluctuate between wide limits. During the period 1910 to 1919 (fiscal years) imports varied from $817,000 in 1916, to $1,545,000 in 1911. The general average was well over $1,100,000. The war caused a reduction in the imports due to the disturbed conditions in France and to the elimination of the Bohemian industry.

TARIFF HISTORY.

Imports of imitation gems were dutiable at 10 per cent ad valorem under the tariff acts of 1883, 1890, and 1894. In 1897 the rate was increased to 20 per cent and had been held at that figure in all acts since that time.

COMPETITIVE CONDITIONS.

Domestic jewelry manufacturers using imitation gems in their product, buy all their stones from importers in New York. The raw material cost is a very small part of the value of the finished stone, labor cost being the chief factor. The same care is given to cutting imitation gems as is expended when cutting precious stones and the success of the foreign industry is due in large part to the experienced labor available for mixing the glass and cutting the product.

of imitation gems is low, when compared with the value ıe article, and high duties would be very little tempta- ssional smugglers. The stones are used in jewelry and luxuries in the same class as parts of jewelry (par. 356).

Court and Treasury Decisions.

The provision in paragraph 357 of the act of 1913 for "imitation precious stones" may well be related to the first provision in the paragraph for precious stones rather than to the clause in which the word "cameo" appears, and it was not intended to relate to anything other than stones which in their natural state are precious stones. The lexicographic meaning of "cameo" does not depend upon whether the substance of which the completed article is composed is a precious stone or is a shell; it is the product of cutting in a certain form wrought upon either shell or precious stone. The process of conversion of a piece of shell into an article like a cameo can not entitle the completed article to be called in any just sense a precious stone simply because cameos may be, and often are, made of precious stones. Earthenware molded in imitation of cameos is not "imitation precious stones" but earthenware ornamented or decorated or manufactured in chief value of such ware. (Wedgwood *v.* United States, 7 Ct. Cust. Appls., 434, of 1917.) Molded glass articles accurately cut to represent brilliants were held dutiable

res of paste under paragraph 95 for large sizes and as
cious stones under this paragraph for small sizes.
, of 1915.) Hatpin tops of glass or paste, although
tation precious stones, are not suitable "for use in the
of jewelry," as, when completed, the hatpins would not
jewelry. (G. A. 7400, T. D. 32883, of 1912.) No limi-
the size of imitation precious stones is prescribed and
xceeding 1 inch in dimensions for jewelry come within

PREFACE.

This is one of a series of Tariff Information Surveys prepared by the United States Tariff Commission and transmitted to the Committee on Ways and Means. The series covers all of the articles and commodities provided for in the tariff act of October 3, 1913, and others not specifically provided for. It is arranged in the numerical order of paragraphs of that act.

In some cases two or more paragraphs have been combined in one pamphlet. In doing this industrial relationship of the articles has been followed when possible. In those instances where a paragraph has been treated under a preceding paragraph of the tariff act reference is made to this fact at the point where the paragraph appears in numerical order. Where one grade of an article is dutiable and another grade of the same article is on the free list, the article is discussed under the dutiable paragraph which appears first in numerical order in the tariff act. In certain instances articles of close industrial relationship and which occur in separate paragraphs of the tariff act have been combined under one paragraph for convenience of discussion. Reference is made to this fact at the point where the commodities would naturally occur in numerical order.

The first pamphlet in the series is an "Introduction and Index," which contains—

1. An introductory chapter discussing the scope of the series and the general method of treatment.
2. An alphabetical index of the articles provided for in the tariff act of 1913, showing the paragraph of the act in which the article is provided for and, if discussed under a different paragraph, the number of such paragraph.
3. A list of the pamphlets in the series, showing the paragraphs and articles included in each pamphlet.

Thus by use of this "Introduction and Index" the exact location of the discussion relating to a given article or commodity can be ascertained.

In the preparation of this report the Tariff Commission had the services of Constant Southworth, of its staff, and of others.

JACQUARD DESIGNS.

TARIFF ACT OF OCTOBER 3, 1913.

Par. 328.—Jacquard designs on ruled paper, or cut on Jacquard cards, and parts of such designs, * * * 25 per centum ad valorem.

GENERAL INFORMATION.

DESCRIPTION AND USES.

Jacquard designs or Jacquard cards are used with the Jacquard loom, a machine for fancy weaving, having a chain of perforated cards passing over a rotary prism. The perforations permit the passage of wires that determine the raising of warp threads, causing the figure to be woven in accordance with the prearrangement of the perforated cards.

DOMESTIC PRODUCTION AND IMPORTS.

Jacquard designs used in the United States are almost exclusively domestically produced. They are made by punching holes in pieces of cardboard with a plate (or a piano) punching machine. Imports compared with domestic production are of no importance. They are accounted for in part by the fact that one American company weaving with Jacquard looms has a mill in France which sends for reference to the American mill copies of the designs it produces.

Imports of Jacquard designs and their parts increased from $1,906 worth in the fiscal year 1907 to about $11,000 worth per year in the three fiscal years 1912 to 1914. During the war imports fell rapidly, amounting to only $14 in the fiscal year 1918. In 1920 they increased to $7,059, and in 1921 to $11,293.

TARIFF HISTORY.

Jacquard designs first received separate mention in the tariff law of 1897, when they were made dutiable at 35 per cent ad valorem. The duty remained the same by the act of 1909. The act of 1913 lowered it to 25 per cent. No effect of the different rates on the amount of imports is to be traced.

1897	402	* * * all Jacquard designs of one line paper, or parts of such designs, finished or unfinished.	35 per cent ad valorem.
		All Jacquard designs cut on Jacquard cards, or parts of such designs, finished or unfinished.	Do.
1909	415	Jacquard designs on ruled paper, or cut on Jacquard cards, and parts of such designs, * * *.	Do.
1913	328	do	25 per cent ad valorem.

Court and Treasury Decisions.

Jacquard drafts on point paper, and Jacquard cards, the designs having been used as patterns and drafted on the point paper and then by that means transferred to or cut on the cards, were held dutiable under the act of 1897 as though imported separately and not as an entirety. (G. A. 8658, T. D. 29511, of 1909.)

Paper articles consisting of Jacquard designs on ruled paper, and readings from such designs also on ruled paper, necessary for the production of the Jacquard cards for lever lace or Go-through machines, were held to be dutiable under paragraph 415 of the act of 1909. (Abstract 31382, T. D. 33217, of 1913.)

WALL PAPER AND HANGING PAPER.

TARIFF ACT OF OCTOBER 3, 1913.

Par. 328. * * * paper hangings with paper back or composed wholly or in chief value of paper, * * * 25 per centum ad valorem.

Par. 332. * * * all papers * * * not specially provided for in this section, 25 per centum ad valorem.

SUMMARY.

The printing of wall paper (paper hangings) is a separate business in the United States, conducted by firms which buy their unprinted paper (hanging paper) from paper mills. Hanging paper is to a large extent produced by mills whose main output is newsprint paper, the production of hanging paper, which closely resembles newsprint in appearance and material used, being subsidiary to filling large contracts for newsprint. In the calendar year 1920 the production of hanging paper amounted to 113,824 tons and that of wall paper to 99,511 tons. In 1921 only 69,725 tons of hanging paper were produced. The production of hanging paper fluctuates considerably from month to month, according to the time that the machines are allowed to suspend newsprint making in order to operate on hanging paper.

There is no tariff problem in hanging-paper manufacture. Both imports and exports, although not separately stated, are undoubtedly small. At the present time the domestic wall-paper industry meets little foreign competition. Although in 1914 imports amounted to 6 per cent of domestic production, in 1919 the United States imported only 0.43 per cent by value of domestic production, and exported 3.90 per cent. Since that time, however, imports have increased and exports have decreased. In 1919 exports of wall paper amounted to $899,457, while imports were only $99,674. In 1921 exports amounted to $590,549 and imports to $355,760. The last-named figure equaled probably between 1 and 2 per cent of domestic production.

Imports come almost exclusively from Germany, the United Kingdom, and Japan. Before the war Germany held first place in the international wall-paper trade. Her total exports were four or five times those of the United States. In our own markets in 1913 Germany sold wall paper amounting in value to 4 per cent of domestic production. The United Kingdom exported to us much more than she imported from us, but was also a large importer of wall paper from Germany.

General Information.

DESCRIPTION.

Two varieties of paper are treated in this discussion. The first, wall paper, or paper hangings, is printed or decorated paper used for covering the interior walls of buildings. It is covered by the provision for paper hangings in paragraph 328 of the tariff act of 1913. Hanging paper is the paper used for making wall paper, i. e., it is wall paper not yet printed or decorated. There is no separate provision for it in the tariff law of 1913. Hanging paper is practically the same in appearance and substance as newsprint paper, except that it is heavier. In Canada it is classed as a variety of newsprint.

The principal variety of hanging paper is that designated as No. 2, an uncolored, untreated paper. By far the greater part of the hanging paper output consists of this kind. There are also certain kinds which are specially treated before they leave the paper mill, some of which do not have to be subsequently printed in a

wall-paper mill in order to be used for interior decoration. Among these are oatmeal and tile paper. Oatmeal paper is paper made by adding wood flour to the pulp in the beater just before the pulp is run over the paper machine—a process which makes little white specks visible in the finished paper. The pulp is usually colored in the beater, but the wood flour does not absorb the color in the short time it remains in the beater. Tile paper is specially embossed and colored to resemble tile.

In this discussion the term "hanging paper" will be used throughout to denote the No. 2 grade and also these special varieties, whether or not they are to be subsequently printed in a wall-paper mill. The term "wall paper" will be used to denote the printed or decorated hangings.

DOMESTIC PRODUCTION.

Rank of industry.—The output of hanging paper is less than that of any other grade of paper separately reported by the Federal Trade Commission; in 1920 it was less than one-twentieth of paperboard production and about one-fifteenth of newsprint production. As very little is imported or exported, practically the same paper appears again as finished wall paper, except for the small amounts of special hanging paper which are used unprinted for interior decoration.

Materials.—Hanging paper is made from practically the same materials as newsprint paper, namely, mechanically ground wood pulp, sulphite wood pulp, clay filler, alum sizing, and sometimes some coloring. However, a slightly larger proportion of ground wood is used in making hanging paper. Newsprint uses about 80 per cent ground wood and 20 per cent sulphite, and hanging paper about 85 per cent ground wood and 15 per cent sulphite. A greater proportion of sizing is necessary for hanging paper to insure against its breaking when applied with paste to a wall. Oftentimes about 10 per cent of clay is added to make the paper opaque and give it a suitable surface. Some manufacturers of wall paper, however, object to using hanging paper with a clay filler, because the clay gradually gets into the printing rollers and gums them up.

The question of raw material is the same for the hanging paper and newsprint industries, because hanging paper is often merely an incidental product of a newsprint mill. Either variety can ordinarily be made at will on the same machine. Consequently, as long as a shortage of wood pulp for newsprint exists, it will be felt in the case of hanging paper also, for no manufacturer is likely to devote to making hanging paper wood pulp that manufactured into newsprint would bring a better price—that is, the price of hanging paper must be at least equal to that of newsprint before a manufacturer will make hanging paper. As long as the present large demand for and high prices of newsprint continue, this limitation must be an important one.

The finished wall paper is made out of hanging paper in connection with all kinds of colors and clay coating materials. Obtaining a sufficient supply of hanging paper depends merely on the willingness of a wall-paper manufacturer to pay enough for it to induce the paper mill to make it in preference to newsprint. There is no tariff problem, as hanging paper supplies are practically all domestically produced.

The colors and other coating materials used in treating hanging paper are now largely of domestic production, although they were formerly principally imported. Many wall-paper concerns have their own color manufacturing plants. The colors used are pulp colors, usually made from coal-tar dyes. China clay, both the domestic and that imported from England, is used to some extent, although the domestic is regarded by many manufacturers as inferior to the English grade.

Methods of production.—Hanging paper: The process of manufacturing hanging paper usually does not differ from that of making newsprint,[1] except that, as already stated, slightly different proportions of raw materials are used. Fourdrinier machines are used interchangeably for either grade. The paper, as it comes off the Fourdrinier machine, differs in appearance from newsprint only in that it is heavier and sometimes has been colored in the beater. To a very limited extent Harper Fourdrinier machines[2] and cylinder machines[3] are used in making hanging paper.

Great care must be taken to secure ground wood with fibers comparatively free of each other, resembling sulphite fibers as closely as possible, because the paper to be made is fairly heavy and the machine, operating at a high speed, quickly eliminates the water in the pulp. As noted, considerable sizing is necessary to produce pliability. The paper must not be overdried; otherwise it becomes brittle and is practically worthless.

Oatmeal hanging paper, as stated above, is made by adding wood flour and also usually coloring matter to the pulp in the beater.

The users of hanging paper have adopted a uniform weight system on the unit weight basis of a ream containing 480 sheets of 24 by 36 inch paper. The weights range from 34 pounds per ream of so-called 9-ounce paper to 74 pounds per ream of so-called 18-ounce paper. The ream serves only as a weight basis, the paper being actually sold in pieces 9 yards long and 19⅜ inches wide.

Newsprint paper weighs usually about 32 pounds per ream of 500 sheets, 24 by 36 inches. The lightest hanging paper (9-ounce size) is figured on the newsprint weight basis (500 sheets per ream) would weigh between 35 and 36 pounds. The heaviest (18-ounce size) would weigh 77 pounds. The comparative lightness of newsprint is apparent.

Wall paper: The printing and decorating of wall paper are processes outside the realm of paper manufacture, being the converting of paper as a crude material into a finished commodity. Wall paper printing and newspaper printing are parallel stages in advancing paper to the finished product.

The rolls of hanging paper, usually containing paper 19⅜ inches wide, are received at the wall-paper mill and placed in the storeroom. When needed they are taken to the printing room. This must be a very long room, for the paper printed at one end must be dry when it reaches the other end. The paper is led over a printing or pattern machine. This is a round structure about 12 feet high, superficially resembling a Ferris wheel, although it is stationary on its own axis. Revolving maple rolls are placed at regular intervals around its

[1] See Tariff Information Survey, Printing Paper.
[2] See Tariff Information Survey, Tissue, Bibulous, and Filter Paper.
[3] See Tariff Information Survey, Paper Boards.

surface, their axes in a horizontal position. Each roller has a pattern made usually of brass studs which have been put in it previously by expert pattern makers; also some metal rollers are used. The lower part of each roller revolves in a separate trough containing the liquid coloring material, which has been mixed in a special mixing room out of pulp dyes. The rollers are spaced in such a way that each one prints its part of the finished design in the proper place, so that the aggregate of the designs printed in different colors by the different rollers is the complete design of the finished paper.

Sometimes before the paper is led over the printing machine it is given a preliminary "drowning" process. This consists merely in coating it on one side with English china clay, with a zinc solution or with some other material that gives a uniform background on which to print the design.

After the paper leaves the printing machine it is draped over the rungs of a sort of continuous horizontal ladder conveyor, which is placed near the ceiling, and passes down the length of the room in the form of festoons. A blast of hot air dries it. At the end of the room it is rolled up.

An elaborate sample room is a necessary part of a wall-paper mill, because, unlike other kinds of paper, there can be no standardization of product. Each design must be selected separately, and the samples must be fairly large in order that from them the effect of the designs on the wall may be adequately judged.

Organization.—The wall-paper mills are usually separate from the hanging-paper mills and purchase their crude paper.

There were 26 mills producing hanging paper in July, 1922. In most instances they are fairly large, for as in the case of other kinds of paper, even a small equipment of beaters, Jordan refining engines, and Fourdrinier machines requires considerable floor space and capital investment. Moreover, a number of the concerns producing hanging paper are among the most important newsprint companies, making newsprint as their major product, and operate huge mills, with ground-wood plants and sometimes sulphite plants attached. Special varieties of hanging paper other than the common white variety, such as colored and oatmeal hanging paper and the heaviest grades of white, are usually made separate from newsprint manufacture in mills which do not make newsprint.

In 1914, according to the United States Census, there were 48 wall-paper printing establishments in the United States, capitalized at $17,619,896. In 1919 the number of establishments was the same as in 1914. Most of these concerns are also of necessity large, because the machinery is expensive and covers much floor space. Some wall-paper printing establishments have separate dye manufacturing plants and maintain their own print roller designing force.

Geographical distribution.—Two-thirds of the domestic hanging paper is produced in New York State. Wisconsin and Pennsylvania produce most of the remainder. New York is also the principal wall paper State, but Pennsylvania produces nearly as much. New Jersey and Illinois are important wall-paper producing States. Twenty years ago Ohio was third in importance, but her production of wall paper has greatly declined.

Development of the industry.—In 1849, when the wall-paper industry was just beginning, there were only six establishments in the United

States making wall paper, with an output valued at $107,040. The number increased by more than 300 per cent during the following decade, reaching 26 in 1859, with twenty times the 1849 output. In 1869 there were only 15 establishments, with about the same output as in 1859. This decrease in number of mills with unchanged volume of output reflected the process of combination and increase of output per mill which was going on. The number of establishments increased to 51 in 1899, although the output in that year was only two-thirds of the 1914 output. As already noted, there were 49 wall-paper establishments in 1919.

Domestic production and consumption.—Hanging paper: The census figures indicate that production of hanging paper increased from 54,330 tons in 1899 to 96,527 tons in 1914. However, the Federal Trade Commission figures show a decrease in production after 1914, the 1918 production being only 63,268 tons or about two-thirds of the 1914 production. This increased to 92,136 tons in 1919, according to the Federal Trade Commission, but to only 69,445 tons according to the Bureau of the Census. Production in 1920, according to the Federal Trade Commission, reached 113,824 tons, but declined to 69,725 tons in 1921. Monthly production also has varied considerably in amount, as shown in the table of production by months in 1919, 1920, and 1921, page 12. That production can fluctuate so much without detriment to the industry is due largely to the fact that many of the paper machines can be operated on newsprint at will in preference to hanging paper.

This production supplies practically the whole of domestic consumption, although in abnormal times there may be a temporary shortage due to difficulty of securing raw material in connection with an unusually high demand, such as took place in the first half of 1920. Although separate figures for imports and exports of hanging paper are not available, it is certain that both are almost negligible. Canada, the principal foreign source of newsprint, produces practically no hanging paper.

Wall paper: The production of wall paper increased from $10,964,269 worth in 1899 to $23,047,901 in 1919. As already noted, this was an increase from $107,140 in 1849. No tonnage statistics are available until the year 1918, when the Federal Trade Commission began to compile them. The first whole year for which we have figures is 1919 when 91,305 tons were produced, which was almost exactly the same as the production of hanging paper in that year. In 1920, 99,511 tons were produced. In 1921 the compilation of wall-paper production figures was discontinued. Although it is thus impossible to make direct comparison of present production with pre-war production, it can be assumed that in a general way the output has varied in about the same proportion as the output of hanging paper. This, in the last five years, has fluctuated considerably and except for 1920 has been below the 1914 output.

An appended table of production by months in 1919 and 1920, page 12, shows remarkable fluctuations in output from month to month. Both in 1919 and 1920 production was very low during the summer months. Thus the production in June, 1919, was 2,688 tons, in comparison with 10,891 tons in October of the same year.

Production of wall paper in the United States supplies practically the whole of the demand for domestic consumption. Imports in

1919 were less than one-half of 1 per cent of production, although in 1914 they amounted to nearly 6 per cent. In 1921 they were probably between 1 and 2 per cent of production.

Domestic exports.—The value of exports increased from $297,307 in the fiscal year 1910 to $1,251,743 in the calendar year 1920. There were some fluctuations, but the general tendency was toward an increase. Exports decreased to $590,549 in 1921. The larger figures of recent years are due in considerable part to an increase in price per unit. In 1914 exports amounted to 2.85 per cent of domestic production and in 1919 to 3.90 per cent. The proportion in 1921 was probably somewhat smaller than in 1919.

Ordinarily Canada has received more than half of the exports of wall paper from the United States, and the United Kingdom, Mexico, Argentina, Chile, Colombia, Australia, and New Zealand have received more or less scattering amounts. In 1919 France, Newfoundland and Labrador, and Brazil were also rather important in the export trade in wall paper.

In Germany, before the war, American wall paper was not able to compete on the basis of price with the domestic product. Only American wall paper with special taste and distinctiveness of design could be marketed in Germany. American exports to Germany were very small, although Germany shipped wall paper to the United States in greater quantities than did any other country.

FOREIGN PRODUCTION.

Separate figures for hanging and wall paper production in the three countries of importance as sources of imports of wall paper, namely, Germany, the United Kingdom, and Japan, are not available. There are about 60 wall-paper factories in Germany. The United States and Germany are the two most important producers of wall paper in the world. Their relative position is difficult to determine, but the United States probably leads. Canada in 1919 produced 7,463 short tons of hanging paper, valued at $574,191.

IMPORTS.

Hanging paper.—No separate statistics are available.

Wall paper.—The value of imports for consumption of wall paper increased from $671,904 in the fiscal year 1907 to $1,052,792 in the fiscal year 1913. After 1913 it decreased steadily to $99,674 in the calendar year 1919. In 1920 and 1921, however, it amounted to $361,363 and $355,760, respectively.

In the fiscal year 1914, when imports were practically at their high point, they were slightly less than 6 per cent by value of domestic production. In the calendar year 1919 they amounted to 0.43 per cent of domestic production. In 1920 and 1921 it is probable that the proportion of imports to domestic production was between 1 and 2 per cent.

Germany was formerly our great competitor, both in export markets and in our domestic trade. In 1913 Germany sent the United States wall paper amounting in value to $646,358, or approximately 4 per cent of our total domestic production. After the fiscal year 1914, however, German exports to the United States

declined, and in 1917 ceased entirely. In the calendar year 1919 they began again in a small way, and by 1921 they amounted to nearly one-half of the imports of wall paper. The United Kingdom and Japan rank next in importance as sources of wall paper.

TARIFF HISTORY.

Paper hangings have been dutiable at 25 per cent ad valorem by every tariff act from 1883 to 1913, except that of 1894, by which they were dutiable at 20 per cent.

No effect of the tariff rate on imports is discernible, for the rate has been practically constant, and imports into the United States increased steadily up to the outbreak of war, when hostilities caused their decrease to a small fraction of their pre-war volume.

PRICES.

The following table shows the range of contract and open-market prices, and where available the average prices f. o. b. mill, actually paid by wall-paper consumers for No. 2 white hanging paper, per 100 pounds, during specified months in 1919 and 1920:[1]

Month.	Range.		Average.	
	Contract.	Open market.	Contract.	Open market.
1919:				
January	$6.00 $6.00	$6.20 $6.50		
April	7.00 8.00	8.00 8.50	$8.00	$8.00
July	8.00 8.00	8.00	8.00	8.00
October	8.00 8.50	8.00 8.50	8.00	8.00
1920:				
January	8.00 8.50	8.00 7.00	8.50	8.00
April	8.00 11.50	8.00 11.50	9.00	9.00
July	8.00 12.00	7.00 11.50	9.00	10.00
October	8.50 12.50	11.00 12.50	11.00	10.00
December	8.00 12.00	7.00 12.50	10.00	9.00

Until after July in 1919, the open-market price lagged behind the contract price. From October, 1919, for somewhat more than a year, on a rising short of supplies, the average open-market price paid by wall-paper makers was considerably higher than the contract price. By December, however, the open-market price had fallen below the contract price. Although the range of contract prices increased between October and December, 1920, the average contract price declined slightly. The hanging-paper market has manifested much the same fluctuations as the wall-paper market.

COMPETITIVE CONDITIONS.

Hanging paper. The United States is practically free from foreign competition in hanging paper. Countries like Germany, which before the war had a large export trade in wall paper, preferred to manufacture their hanging paper into wall paper before exporting it.

[1] The compilation of statistics on hanging paper was discontinued in 1921.

Wall paper.—That the industry is not subject to very dangerous foreign competition is demonstrated by the fact that in the calendar year 1919 exports of wall paper amounted to $809,457 as compared with imports of $99,674. Imports into the United States in 1919 amounted only to 0.43 of 1 per cent of production. Even in 1921, when industry in general was suffering from depression, imports amounted probably to only between 1 and 2 per cent of production, while exports amounted to one and one half times imports.

Before the war, as now, Germany, the United Kingdom, and Japan were the only countries that sent wall paper to the United States in significant amounts. In 1914 imports were nearly 6 per cent of domestic production. Of these three countries, Germany was the only serious competitor. In 1913, a representative pre-war year, Germany sent the United States $646,353 worth of wall paper in spite of the 25 per cent tariff. This was about 4 per cent of domestic production in that year. On the other hand, in the same year the United States sent to Germany only $16,725 worth of wall paper. Furthermore, Germany was far ahead of the United States as a general exporter of wall paper. In 1912 and 1913 she exported $2,257,200 and $2,180,300 worth, respectively, of wall paper in comparison with total domestic exports of $399,121 and $482,836 in the same years. The actual amounts of these exports were 13,947 and 13,197 short tons—undoubtedly from 15 to 20 per cent of American production. Germany was the dominant figure in the world's wall-paper market. It was reported just before the war from Germany that overproduction in wall paper prevailed. Prices were much lower than American prices.

Our wall-paper trade with the United Kingdom was not so one-sided. In 1913 and 1914 we imported from her $236,395 and $222,667 worth, respectively, and exported to her $50,164 and $40,971 worth. The United Kingdom herself used to be one of the largest importers of German wall paper.

Japanese exports to the United States were not in such volume as to offer serious competition.

COURT AND TREASURY DECISIONS.

Papers colored and embossed to imitate leather and papers coated with a [illegible] to imitate velvet were held dutiable under the act of 1883 as paper hangings. (Dejonge v. Magone, 159 U. S. 562.)

Stamped-out paper reliefs in floral designs on separate sheets about 15 inches long and 12 inches wide, and which were used as papers for wall paper, being applied to a background of solid color by paste, were held dutiable as paper hangings under the act of 1897 (Abstract 10808, T. D. 27280), as were an article composed of cotton and gilt paper, the latter chief value, and chiefly if not exclusively used as wall paper (G. A. 5976, T. D. 26185); so-called grass cloth with a paper backing, grass cloth chief value, on the ground of its being "uniformly and generally classed throughout the country as within that class of goods known as paper hangings" (G. A. 6202, T. D. 26850), and hand painted paper hangings (G. A. 6586, T. D. 28157).

White paper in reels or rolls 19¼ to 22 inches wide imported for use as a material for paper hanging was held to come within the provision in paragraph 415 of the act of 1909 against the importer's contention that it was dutiable under paragraph 409 as printing paper suitable for printing books or as paper not specially provided for. Government counsel conceded that the importation was material for paper hangings, properly classable as paper not specially provided for. (Thomas v. United States, 2 Ct. Cust. Appls. 397.) Paper hangings were denominatively provided for in paragraph 415 of that act without restriction as to the manner of their printing and, accordingly, included lithographically printed paper in rolls 18 inches wide in designs forming repeats of from 5 to 30 feet and used as papers or friezes for wall hangings. (G. A. 7434, T. D. 33214.)

WRAPPING PAPER.

TARIFF ACT OF OCTOBER 3, 1913.

Par. 328. * * * wrapping paper not specially provided for in this section, 25 per centum ad valorem.

SUMMARY.

Wrapping paper ranked third in paper production in the United States in 1921, being surpassed only by newsprint paper and paper boards. The principal seats of industry are in Maine, New Hampshire, New York, Pennsylvania, and the Lake States.

The tariff problem is not a pressing one. Imports are in very small volume and amount to less than exports. From the beginning of the war until 1921 the wrapping-paper industry was practically free from foreign competition, although before the war Germany and Scandinavia exported in moderate quantities to the United States. Imports from Europe fell off during the war, and from 1917 to 1920 Canada was the only foreign source of importance, although she sent to the United States less than one-half of 1 per cent of domestic production. In 1921, however, shipments from Sweden and Germany began again, and total imports increased from 0.22 of 1 per cent of domestic production in 1920 to 0.71 of 1 per cent in 1921. Exports, which from 1916 to 1920 averaged more than 30,000 tons per year, decreased in 1921 to 13,022 tons, or 1.66 per cent of domestic production.

General Information.

DESCRIPTION.

As its name indicates, wrapping paper is used for wrapping and packing purposes of all sorts. This is practically its sole use. There are, however, three principal varieties according to material used: (1) Kraft, a very tough brown paper made wholly or in part of sulphate wood pulp, introduced within the last 15 years; (2) manila, a strong paper of lighter color, formerly made principally of old and waste manila rope and rope ends, hemp, jute, and flax waste, old gunny cloth and old gunny bags, but now made chiefly of sulphite wood pulp, and frequently called bogus manila; and (3) fiber paper, a cheap, more or less brittle and tearable variety made of waste paper, cuttings from paper-board factories, mechanically ground wood pulp, wood-pulp refuse, or almost any fibrous material of inferior quality. Of these three sorts, genuine manila made of old rope, bagging, etc., is the strongest per unit of weight. Next comes kraft paper, and then the best grades of wood pulp or bogus manila. Last, of course, are the fiber papers of common stock. In addition to these varieties, there are a number of cheap wood-pulp papers made of ground wood with varying proportions of chemical pulp.

Bag paper is made of all the different substances above listed. Paper to be made into sacks for flour, cement, charcoal, sugar, nails, etc., is necessarily heavy and tough and often is reinforced by cloth.

There are a great many special kinds of wrapping paper, all of which may be classified under the varieties already named. Mill wrapper is a thick, coarse paper, used to a great degree in paper mills, where it is made to pack the staple products of those mills. It is made often out of paper-mill sweepings. So-called news wrapping paper comes under the head of fiber paper, the raw material being repulped newsprint. Straw wrapping paper, screenings (paper made from pulp screened out as unfit for use in the paper for which it was originally intended), express paper (primarily for wrapping express shipments), fruit wrappers, and silk wrappers are other varieties. Certain kinds of tissue paper are used for wrapping purposes, but are

treated separately in the tariff and bear a higher rate of duty. Grease-proof paper and imitation parchment are also mainly used for wrapping. A special survey treats these grades.

Wrapping paper is an essential in the wholesale shipment of a great many commodities, and of course its use in the retail trade is almost universal. Of recent years cardboard cartons have, however, come into use as substitutes for wrapping paper in the retail trade.

DOMESTIC PRODUCTION.

Size of industry.—The wrapping-paper industry ranks third in paper production in the United States, the output of newsprint paper and that of paper boards each being larger both in tonnage and in value. As in the case of these other varieties, the industry producing wrapping paper is a large and important one. It supplies practically all American users of wrapping paper, imports being very small. The following table shows comparative production of the three principal kinds of paper in 1921:

	Tons.
Paper boards	1,664,931
Newsprint	1,226,189
Wrapping paper	651,605

Materials.—The principal materials used in the manufacture of wrapping paper are chemical wood pulp, ground wood, old rope and hemp, jute, flax, tag, and gunny refuse, straw pulp, waste paper, and old fibrous material of almost any kind whatsoever. Sulphite wood pulp, used in the manufacture of bogus manila, is the raw material consumed in greatest quantity. Considerable sulphate pulp and some soda pulp is used in making kraft paper. Ground wood enters to some degree into the manufacture of the cheaper grades of wrapping paper. The shortage of wood pulp of all kinds threatens to be serious. The subject of our supply of wood pulp and its relation to Canada is discussed in another survey. The availability of material, however, is not affected by the tariff. Wood pulp and pulpwoods come in duty free. Canada and Sweden are the principal sources.

Old rope, waste rope, rope ends, flax, jute, and hemp waste, old gunny cloth, and old gunny bags are imported free as paper stock. Imports supply a considerable portion of the domestic consumption of these materials, which are used in making true manila paper. However, there is no shortage in the supply of these materials. Waste paper and waste fiber of other sorts are available in large quantities here in the United States, very little being imported.

Equipment.—Wrapping-paper machinery used in the United States, like machinery employed in making other kinds of paper, is manufactured almost entirely in this country, and is of excellent quality. The American manufacturer can obtain his machinery at least as advantageously as the manufacturer in any other country.

Methods of production.—The fiber is prepared in the beater just as in the case of newsprint and paper boards. Refuse from jute, flax, and hemp, including old rope and bagging, is subjected to a special chemical treatment in advance, just sufficient to isolate the fibers to a condition in which it is possible to work them up into paper. The bagging and rope are cut in a rag chopper and boiled in revolving boilers with lime or caustic soda for several hours at a pressure of 20 to 30 pounds, the lime being used when it is desired to manufacture

a harsh paper and the caustic soda being employed to make paper of a softer texture.

Waste papers are handled in several ways, being softened and pulped in large tanks, in edge runners (machines for mechanical separation of the fibers without shortening them), in special pulping machines, or else direct in the beater.

In the beater the stronger materials, such as jute or old rope and string, are either used by themselves or are blended with inferior raw material, according to the quality of the paper being made. The hemp and jute fibers are generally beaten separately before the other materials are added. The pulp is mixed with the required amount of loading, while the sizing and coloring operations are carried out in the usual way.

Most wrapping paper is made on the Fourdrinier machine, in exactly the same way as printing paper, described in another survey. Certain light wrappings, however, usually glazed on one side, are made principally on a modification of the Fourdrinier machine, called the single-cylinder or Yankee paper machine. The wet end of the machine, onto which the wet pulp is fed, is the same as that of the Fourdrinier machine. As in the case of the latter the beaten pulp passes from the stuff chest onto a moving wire and through the press rolls. But instead of being dried over a number of cylinders, the paper is led over one single cylinder of very large diameter which is internally heated with steam. The paper is usually pressed against the surface of the cylinder by means of a heavy felt. The side of the paper coming into contact with the cylinder becomes highly polished, the surface in contact with the felt remaining in an unfinished rough condition.

Organization.—The wrapping-paper industry, like every branch of the paper industry, is in the hands of a comparatively small number of large mills. A wrapping-paper mill is of necessity a large affair, requiring permanent installations of expensive machines and a large amount of capital. Wrapping paper making can not be undertaken by anyone not willing to devote years of labor and a great deal of money to the enterprise. It takes ordinarily about two years to erect a mill and get it in operation.

Because wrapping-paper machines can ordinarily be used also for making newsprint (as also oftentimes newsprint machines for making wrapping paper) it sometimes happens when the price of newsprint is unusually high, as in the shortage of 1920, that the conversion is made from wrapping paper to newsprint. This of course decreases the available supply of wrapping paper and increases the available supply of newsprint.

In July, 1922, 147 mills were reported to be manufacturing wrapping paper. According to Lockwood's Directory the concerns owning these mills were divided as follows in the manufacture of the different kinds of wrapping paper:[1]

Wrapping paper (not further specified)	80	Rag wrapping paper	19
Manila paper	64	Sack, flour, cement, charcoal, sugar, and nail bag paper, etc	17
Fiber paper	51	Straw wrapping paper	10
Kraft paper	37	Fruit wrapping paper	9
Bag paper	31	Butcher's manila paper	7
Mill wrappers	27	Packing paper	6
Express paper	20	Silk wrappers	3

[1] This tabulation is based on conditions of manufacture obtaining in 1922.

course, in a great many cases a single concern manufactures
l of the varieties of paper named.
ociations.—A considerable number of the wrapping paper
acturers of the United States are affiliated with the Wrapping
Manufacturers' Service Bureau.
graphical distribution.—Bogus or wood manila is produced
r in Maine, New York, Wisconsin, and New Hampshire. Wis-
n is the principal kraft State. Real manila is manufactured
y in New York, Ohio, and Pennsylvania. Heavy mill wrappers
nade chiefly in Pennsylvania, New York, Wisconsin, and Ohio.
of the straw paper output comes from Ohio and New York.
onsin, Michigan, Pennsylvania, and New York produce the
est amounts of other kinds of wrapping paper.
istory of the industry.—The history of the domestic wrapping
er industry has no particular tariff significance, except perhaps
he growing dependence on other nations for chemical wood pulp.
s dependence arises from the development of bogus manila and
ft production and the increasing domestic shortage of wood pulp.
e tendency is away from the use of jute and hemp wastes and toward
creased use of chemical wood pulp. It is not a tariff problem,
owever, that is engendered in this shift of dependence on raw
aterial, but rather a problem of developing new and reliable sources
f supply. In this connection the proposed reforestation of denuded
reas in the Eastern and Lake States and the tapping of the Western
States and Alaska's pulpwood forests are of much significance for
he future.

Domestic production and consumption.—The total production of wrapping paper in the United States increased from 535,252 short tons, with a value of $24,542,373, in 1899 to 881,799 tons, valued at $49,372,753, in 1914. After 1914 there was no increase until 1920 when production was 831,889 tons. In 1921, a year of abnormal depression, only 651,605 tons were produced. The increase in wrapping paper production in the last 22 years has proceeded at a rate much slower than that of any of the other important kinds of paper. Where newsprint nearly tripled, fine paper more than tripled, book paper nearly quadrupled, and paper boards more than sextupled their output between 1899 and 1920; wrapping paper increased its output by almost one-third. The increasing substitution of cartons for paper in wrapping articles in the retail trade partly accounts for the slow increase in production. The paper board industry has here profited at the expense of the wrapping paper industry.

Appended tables (p. 25) show production by States and by varieties for census years 1899 to 1919. Although in 1914 bogus manila was made in greatest quantity, in 1919 kraft paper led in amount of production. Production of manila paper (from rope, jute, tag, etc.) and of heavy wrapping paper (mill wrappers, etc.) increased between 1914 and 1919. The production of straw wrapping paper, important in 1899, had almost ceased by 1919.

Next to newsprint and book paper, wrapping paper uses the greatest supplies of wood pulp. The greatly increased demand for newsprint paper after the war reacted to diminish the supply of raw material for wrapping paper. During the first three quarters of 1920 high-grade sulphite and sulphate pulp were so difficult to obtain that manufacturers of kraft and the better grades of wood

manila were unable to meet the full demand. This shortage of wood pulp is discussed in the survey on wood pulp. The ultimate remedy for such shortages will have to be reforestation in the East, the development of the pulpwood forests of the Pacific Northwest and Alaska, or increased supplies from Canada.

There is plenty of old rope and bagging for manufacturing genuine manila paper, as well as plenty of waste paper and waste fiber of other kinds for the cheap grades of wrapping paper.

The domestic industry supplies practically the entire American demand, imports amounting to less than 1 per cent of production.

Domestic exports.—Printing paper and wrapping paper have the widest foreign markets of any kinds of paper. From 1916 to 1920, 3 to 4 per cent of the wrapping paper made in the United States was exported. In the fiscal year 1914 only four-fifths of 1 per cent was exported. Exports jumped from 11,515 short tons in the fiscal year 1915 to 32,422 short tons in the fiscal year 1916 and remained at about the same level up to the calendar year 1919, when they increased to 37,458 tons. The year 1920 showed a decrease, with exports of only 30,632 tons. In 1921 there was a decrease to 13,022 tons, or to 1.66 per cent of domestic production.

American wrapping paper is sent all over the world. Since 1915 Cuba has been the largest recipient.

FOREIGN PRODUCTION.

An appended table (p. 26) shows that the world's production of wrapping paper in 1906–7 totaled 1,932,080 short tons. Next to the United States production of 561,800 short tons in that year came Germany's output of 341,290 tons, France's 248,260 tons, the United Kingdom's 197,540 tons, and Austria-Hungary's 102,320 tons. None of these nations, however, is at present in a position to compete with the United States in the domestic market.

Canadian production of wrapping paper increased from 50,360 short tons in 1917 to 61,180 tons in 1918, but decreased to 59,697 tons in 1919. Of the 1919 production, 33,394 tons, or slightly more than half, consisted of kraft; 5,460 tons were heavy mill wrappers; 9,427 tons were bogus or wood manila. Almost negligible amounts of true manila and straw wrapping paper were produced. Canada has possibilities for considerable development in wood-pulp wrapping paper manufacture. It probably costs somewhat less to produce it in Canada than in the United States. The extent of Canada's development in this branch of paper manufacture will be determined largely by the American demand and tariff policy. So far, however, most of Canada's sulphate and sulphite pulp for wrapping-paper manufacture has been sent to the United States to be made into the finished paper.

The following table, compiled from the Papermakers' Directory of All Nations, shows the number of mills in all the different countries of the world producing the principal kinds of wrapping paper. The figures are for the year 1920.

m the table above it will be seen that the western European ıs, notably Italy, France, and Germany, possess a large number ills manufacturing wrapping paper of unspecified grade. In , the number of mills on wrapping paper is greater than in the d States. But the average European mill is considerably er than the American. This fact explains America's much r output. In manila production, the United States possesses y two-thirds of the world's mills; of kraft mills, nearly one- of the world's total. In bag paper mills the United States, ed Kingdom, and Germany are about even. The United States all the express paper mills, three-fourths of the mills producing wrappers, and 21 out of the 27 straw wrapping paper mills in world.

ıis table has been prepared on a somewhat different basis from previous table, which shows the number of mills in the United es manufacturing the different kinds of paper. However, it s some idea of the comparative number of mills in different ıtries, except that mills in disturbed countries such as Russia listed as before the war.

IMPORTS.

Import trade in wrapping paper is of small importance. In the fiscal year 1914 imports were 1.66 per cent of production. From then until 1921 they decreased almost continuously. In the fiscal year 1914 they amounted to 18,258 short tons dutiable and to approximately 7,000 tons free.[1] They had decreased to 2,271 tons in the calendar year 1920, which represents 0.22 per cent of production. In the calendar year 1921, however, they increased to 0.71 per cent of production.

Up to 1915 Sweden was the largest exporter of wrapping paper to the United States. In the fiscal year 1914 she sent us 8,389 short tons dutiable, or 46 per cent of our dutiable imports, in addition undoubtedly to a considerable amount admitted free of duty.[2] Canada, which first began to send wrapping paper in the last quarter of the fiscal year 1912, developed her export to the United States so rapidly that in the fiscal year 1914 she ranked second to Sweden. In that year wrapping paper imports from Canada amounted to 5,186 tons dutiable, or 28 per cent of dutiable imports and probably about half that amount of free imports.[2] Norway, Germany, and Spain ranked nearly equal as sources of most of the remainder.

During the war the wrapping paper exports to the United States of the countries other than Canada declined to almost nothing. Canada's exports decreased also; in the calendar year 1919 they were probably not more than a third their volume in the fiscal year 1914. The total wrapping paper imports in the calendar year 1919 were 2,401 short tons, of which Canada sent 2,369, or 99 per cent. In 1920, however, imports from Europe began to revive. In 1921, out of 5,707 tons of wrapping paper imported into the United States, 2,875 tons came from Sweden and 1,410 tons from Germany. Practically none came from Canada.

PRICES.

In an appended table (p. 29) are shown the prices of the principal kinds of wrapping paper from 1910 to April, 1922. Until 1916 prices were exceedingly steady. In the early part of 1916 they mounted rapidly, those of kraft and true manila increasing in the greatest proportion. The rise continued into 1917. During the latter part of 1917 they decreased, but not to their former level. The year 1918 showed another increase. During 1919 they increased again but rather slowly. This increase continued fairly steadily up to September, 1920, for every kind of wrapping paper listed except No. 2 jute manila and imported kraft, the prices on which remained steady from January to September, 1920, at 11 and 15 cents per pound, respectively, and screenings, the price of which decreased in early September after a steady rise during the year. September prices remained practically unchanged through the middle of December. The only prices that decreased from December, 1920, to January, 1921, were those on jute manila and kraft. Prices remained

[1] The latter figure has been computed by dividing the value of free imports for consumption in 1914 by the average value per pound of wrapping paper imported under a 25 per cent duty in the same year.

[2] Imports of free wrapping paper in the fiscal year 1914 were not segregated by countries and were reported only by value. (See table p. 28.)

rkably firm for a period of business depression. Between ary, 1921, and April, 1922, prices on all grades decreased. pt in the case of jute manila, the decrease was very marked.

TARIFF HISTORY.

ıtil the act of 1909 wrapping paper was not separately provided ı the tariff schedule. It bore an ad valorem duty of 25 per cent ne acts of 1883 and 1890, 20 per cent by the act of 1894, and 25 cent by the act of 1897 as paper not specially provided for. By act of 1909 wrapping paper was separately specified; 35 per cent fixed as the rate of duty. The Canadian reciprocity act of y 26, 1911, admitted free from Canada wrapping paper valued at more than 4 cents per pound, provided Canada placed no export ties or restrictions on such paper or the wood or wood pulp from ıich it was made. This privilege was extended by judicial con-ruction to other nations under most-favored-nation agreements. ne 1913 tariff terminated the Canadian agreement and reduced the ɜneral tariff on wrapping paper to 25 per cent ad valorem.

It is questionable whether the general tariff has had any effect ne way or the other on imports of wrapping paper, for these mports have decreased steadily since the 1913 tariff went into effect, although it lowered the duty from 35 to 25 per cent ad valorem. War conditions have tended to obscure the effect of the change in tariff through their depressing effect on exports from Europe to the United States.

A sudden growth of wrapping-paper imports from Canada took place shortly after the removal of the tariff barrier on July 26, 1911. The following table shows by quarters the value of our free imports of wrapping paper for consumption from Canada during the entire free period:

July 26, 1911, to Sept. 30, 1911	.....
Oct. 1, 1911, to Dec. 31, 1911	.....
Jan. 1, 1912, to Mar. 31, 1912	.....
Apr. 1, 1912, to June 30, 1912	$1,214
July 1, 1912, to Sept. 30, 1912	1,632
Oct. 1, 1912, to Dec. 31, 1912	21,609
Jan. 1, 1913, to Mar. 31, 1913	62,902
Apr. 1, 1913, to June 30, 1913	118,903
July 1, 1913, to Oct. 3, 1913	[3] 366,757

In this case, the influence of tariff removal in encouraging imports seems to be definitely established, although the actual shipments from Canada did not begin until eight or nine months after Canadian wrapping paper went on the free list. The law went into effect on July 26, 1911. Up to March 31, 1912, the United States imported no wrapping paper from Canada. In the last quarter of the fiscal year 1912 free wrapping-paper importations from Canada began. These increased at a very rapid rate until the 1913 tariff law, imposing a 25 per cent duty on all wrapping paper, n. s. p. f., went into effect. The figure for the period from July 1 to October 3, 1913—$366,757—also includes imports of free wrapping paper from other countries during the period July 28 to October 3, 1913; there is no doubt, however, that imports from Canada in that quarter increased over the previous

[3] Includes also imports of free wrapping paper from other countries between July 28, 1913, and Oct. 3, 1913.

quarter. After the imposition of a general 25 per cent duty, imports from Canada steadily declined.

Thus the importation of a commodity not previously imported from the region in question was apparently effected through placing that commodity on the free list, and the reimposition of the duty, if not a cause of, was coincident at least with a decrease in the newly established volume of import.

COMPETITIVE CONDITIONS.

At the present time the wrapping-paper industry of this country has little foreign competition in its domestic markets. In 1921 imports of wrapping paper amounted to 0.71 of 1 per cent of domestic production. Nevertheless, in 1921 Sweden and Germany again began to export small amounts of wrapping paper to the United States, although from 1918 to 1920, inclusive, imports from Europe were negligible. In 1919 and 1920 Canada was the only country that sent wrapping paper to this country in quantities worth noting, and these amounted to less than one-third of 1 per cent of domestic production. Our 1919 exports to Canada of 4,990 tons over a 32½ per cent tariff in comparison with our imports from her of 2,369 tons indicate our present strong position in relation to Canada, in spite of the fact that Canada can probably produce wood-pulp papers somewhat more cheaply than the United States.

Before the war Germany and Scandinavia had to be reckoned with as competitors in wrapping paper, although the amounts they sent to the United States were small in comparison with domestic production. According to manufacturers the shipments from those countries, especially those from Germany, affected the domestic market much more widely than would be expected from the actual increase of the supply on the market by reason of the amounts sent, because the laws of this country made it impossible for domestic producers to combine to purchase the foreign offerings and bring them on the market in an orderly fashion. Hence these offerings were played off against one American manufacturer after another and unduly depressed the market.

Other facts support the belief that the American wrapping-paper manufacturing industry need not fear competition. The wide export field maintained by the United States supports this belief. American wrapping paper is sent all over the world, and not exclusively to countries with no paper industries of their own. For instance, in the fiscal years 1916 and 1917 we sent 8,000 and 7,000 tons of wrapping paper, respectively, to the United Kingdom. In the calendar year 1919 we sent her nearly 2,500 tons, and in 1920, 2,000 tons. No particular danger from Canadian competition in wrapping paper is apprehended by American manufacturers. This is probably due to the fact that there is no such cleavage of interest between American and Canadian paper manufacturers as exists between American and European manufacturers. A considerable part of the capital invested in the Canadian paper industry is American. Moreover, there seems to be a more or less well-defined division of function, particularly in the better grades of wood-pulp wrapping paper. Canada makes the pulp for the wrapping paper, especially sulphate pulp, and sends it to the United States to be made into the finished product. Hence no clash of American and Canadian interest seems likely.

STATISTICAL TABLES.

Production of wrapping paper in United States, by States, 1899–1919.

COURT AND TREASURY DECISIONS.

To constitute a material paper, it is not necessary that the machine used in its manufacture should be known as a paper-making machine, nor that the material shall contain glue, alum, and clay; the product determines its classification. Material having the ordinary thickness of wrapping paper, with the appearance of wrapping paper and used as such, was held not to be wood pulp but wrapping paper and dutiable under paragraph 402 of the act of 1897 as paper not specially provided for. (Germania Importing Company *v.* United States, 2 Ct. Cust. Appls., 55.) Cloth-lined waterproof wrapping paper, consisting of paper with a coating of pitch, and having attached thereto a cotton fabric to give strength and security to the article, was classified by the Treasury Department as a manufacture of paper under paragraph 407 of the act of 1897 (Dept. order, T. D. 28364); oiled and cotton-lined paper declared to be waterproof used for lining packing cases, wrapping automobile tires, etc., was classified as wrapping paper under the act of 1909 (Abstract 25520, T. D. 31568).

To bring a wrapping paper with a decorated surface within the pertinent provision of paragraph 411 of the act of 1909, it was declared necessary to show the decoration was placed on the paper by a separate and independent decorative process; the phrase "whether produced in the pulp or otherwise" was interpreted to include a decorated effect produced by the intentional use for that purpose of a particular kind of felt or felt blanket. (Dunn *v.* United States, 2 Ct. Cust. Appls., 65.) A wrapping paper exhibiting a plaid or checkered design on its surface was held to come within that paragraph as wrapping paper with the surface decorated or covered with a design (G. A. 6937, T. D. 30083).

Brown kraft paper, manufactured in Norway and Sweden and generally used for wrapping paper, was held dutiable as wrapping paper under paragraph 396 of the act of 1897 rather than paragraph 402 of said act as printing paper. (Pritchard *v.* United States, 2 Ct. Cust. Appls., 247, of 1911.)

Wrapping paper imported from Norway answering to the description of section 2 of the Canadian reciprocity act of July 26, 1911, was held dutiable under paragraph 328 of the act of 1913 and not under said section 2, because impliedly repealed by the act of 1913. (Dow Co. *v.* United States, 7 Ct. Cust. Appls., 343.)

Wrapping paper with a surface design, claimed dutiable under paragraph 328 of the act of 1913 as wrapping paper not specially provided for, was held properly dutiable as classified under paragraph 324 of said act as "uncoated papers * * * with the surface or surfaces wholly or partly decorated or covered with a design, fancy effect, pattern, or character, whether produced in the pulp or otherwise, except by lithographic process." The board said that it was not the intention of Congress in framing paragraph 328 to include thereunder all wrapping papers, but only such papers as were not more specifically provided for elsewhere. (G. A. 7843, T. D. 36089, of 1916; followed in Abstract 44916 of 1922.)

PREFACE.

This is one of a series of Tariff Information Surveys prepared by the United States Tariff Commission and transmitted to the Committee on Ways and Means. The series covers all of the articles and commodities provided for in the tariff act of October 3, 1913, and others not specifically provided for. It is arranged in the numerical order of paragraphs of that act.

In some cases two or more paragraphs have been combined in one pamphlet. In doing this industrial relationship of the articles has been followed when possible. In those instances where a paragraph has been treated under a preceding paragraph of the tariff act reference is made to this fact at the point where the paragraph appears in numerical order. Where one grade of an article is dutiable and another grade of the same article is on the free list, the article is discussed under the dutiable paragraph, which appears first in numerical order in the tariff act. In certain instances articles of close industrial relationship and which occur in separate paragraphs of the tariff act have been combined under one paragraph for convenience of discussion. Reference is made to this fact at the point where the commodities would naturally occur in numerical order.

The first pamphlet in the series is an "Introduction and Index," which contains:

1. An introductory chapter discussing the scope of the series and the general method of treatment.
2. An alphabetical index of the articles provided for in the tariff act of 1913, showing the paragraph of the act in which the article is provided for and, if discussed under a different paragraph, the number of such paragraph.
3. A list of the pamphlets in the series, showing the paragraphs and articles included in each pamphlet.

Thus by use of this "Introduction and Index" the exact location of the discussion relating to a given article or commodity can be ascertained.

In the preparation of this report the Tariff Commission had the services of Constant Southworth, of its staff, and of others.

FINE PAPER AND ENVELOPES.

ACT OF OCTOBER 3, 1913.

Par. 326. Writing, letter, note, drawing, handmade paper and paper commercially known as handmade paper and machine handmade paper, japan paper and imitation japan paper by whatever name known, and ledger, bond, record, tablet, typewriter, and onionskin and imitation onionskin papers calendered or uncalendered, whether or not any such paper is ruled, bordered, embossed, printed, lined, or decorated in any manner, 25 per centum ad valorem.

Par. 327. Paper envelopes, folded or flat, not specially provided for in this section, 15 per centum ad valorem.

SUMMARY.

FINE PAPER.

Size and output.—Fine paper ranks fifth in value and sixth in tonnage among the kinds of paper produced in the United States, its 1921 production being nearly equal that of building paper, which was the next higher in the scale of production. The value of the output, however, is almost equal to that of wrapping paper and to that of newsprint paper. The output in 1919 was 343,762 tons, in 1920, 389,322 tons, and in 1921, 242,485 tons.

Relation of foreign commerce to production.—Imports of fine paper into the United States are in exceedingly small volume. The production in the United States at the present time supplies practically the whole of the domestic demand, imports amounting in 1921 to about one-third of 1 per cent of production. In 1914, when importations were largest, they amounted to only 0.44 of 1 per cent of production. Exports, on the other hand, amounted to 4.12 per cent of production in 1914 and increased to 15 per cent in 1919. Exports decreased in 1920 and 1921; yet in the latter year they still amounted to more than six times the imports.

European competitive conditions.—Nevertheless, there is much fear of foreign competition in fine paper. This is due partly to the fact that before the war certain European countries, especially Germany, periodically shipped to the United States amounts of fine paper which, although not large, were sufficient to cause serious disturbances in the American market. Antitrust laws forbade combinations on the part of American manufacturers to mitigate the effects of this practice. Another reason for fearing the potential competition of Germany and other countries is that before the war these countries could obtain skilled labor at a fraction of the price prevalent here. Also certain American manufacturers maintain that on account of the superior training and family continuity of European labor, it is impossible for American manufacturers to turn out as good a product. This is a moot point, some manufacturers declaring that American paper is as good as that made anywhere. It remains true, however, that the greater amount of labor and attention necessary per unit

of output for fine paper as contrasted with cheaper grades gives an advantage to countries producing under the conditions that prevailed in Europe before the war.

Until the war began, protection was adequate, except for the relatively small dumping of paper below production cost which may have occurred. During the last three years of the tariff of 1909 the rate averaged an ad valorem equivalent of nearly 45 per cent. Some manufacturers allege, however, that under the 25 per cent ad valorem rate inaugurated in October, 1913, the industry faced a dangerous competition. It is true that during the fiscal year 1914 imports reached a record volume. Then the war came and upset all existing competitive conditions. Abnormal post-war conditions of foreign competition attendant on depreciated exchange in Europe at present (October, 1922) show few signs of improvement. It is difficult to forecast the duration of the advantage certain European countries are said to enjoy by reason of the depreciation of their currencies.

ENVELOPES.

The envelopes referred to in this discussion include a large number made from kraft and manila papers in addition to those of fine paper. The industry in 1919 was in the hands of 106 concerns, capitalized at $24,754,818. Most envelopes are made by separate envelope manufacturing concerns, although some are made by the concerns making fine paper. Production in 1919 was valued at $39,664,077.

There is no tariff problem involved in the envelope industry. Imports in 1919 amounted to only four-hundredths of 1 per cent of domestic production.

Summary table [1]—Fine paper.

Year.	Domestic production.[2]	Imports for consumption.	Domestic exports.	Ratio to production.[3] Imports.[4]	Ratio to production.[3] Exports.[5]

General Information.

DESCRIPTION.

Fine paper, as is evident from its tariff classification, has a great many subdivisions. It consists of paper made from a high grade of raw material, principally cotton and linen rags, also cotton linters, esparto, and special fibers. Sulphite wood pulp, however, is being used increasingly in making writing paper. It is impossible to exclude such medium-grade writing papers as those containing wood pulp from the general heading of fine paper, because it is desirable to treat together all classes of writing paper.

Writing paper and other fine papers are much the same in texture and in the raw material used as certain high grades of book paper, except that watermarks and special finishes are used to a much greater degree. Some of the paper described in this discussion is used for printing purposes. However, this amount is relatively

small, and is better considered in connection with fine paper than with book paper.

Classification.—It is impossible to differentiate satisfactorily the manifold varieties of fine paper. This is particularly true with the principal group of fine papers, namely, writing papers. Writings, bonds, and ledgers are classified separately, yet bonds and ledgers are actually writing paper. There is no uniform system of classifying bonds, ledgers, papeteries, or linens by raw-material content, by size, or by the use to which they are to be put. Every variety overlaps one or more varieties to some extent. Some varieties bear two names, such as "linen bond." In actual practice, in the mill, the product will often be named according to the dimensions of the finished sheet turned out, because the mill ordinarily sells sheets of certain standard sizes to makers of papeterie, other standard sizes to makers of bond, and yet others to makers of ledgers.

Bonds, ledgers, papeterie.—In general, however, the distinctions in terminology are as follows: Bond paper (which derives its name from the fact that it was first used as paper for engraving bonds) is usually of medium weight, is not highly calendered, and hence has not a highly polished surface, and tends to be translucent. When handled, it often has a tendency to rattle. The cheapest bond paper is made of pure sulphite wood pulp and the best of 100 per cent new linen rags. Intermediate grades are made of various proportions of sulphite and old and new cotton and linen rags.

Ledger paper is usually harder, tougher, and has a more polished surface than bond paper. Oftentimes it is heavier also. There are no bond papers of as great a weight as the heaviest ledger papers. A smooth polished surface on which erasures can easily be made is necessary, for ledger paper is most frequently used for bookkeeping, public records, and similar purposes. Strength and durability are also naturally requisites of this sort of paper. It is consequently ordinarily made entirely or in greater part of rags.

Papeterie is the term applied to writing papers for putting up in boxes as stationery. It differs usually from bond and ledger in having a rather soft, coarse texture. It has a dull, rough finish, for, like bond paper it often is not calendered. It is usually rather heavy.

Linen.—Of all the terms for writing paper the word "linen" is perhaps the most loosely used. Mr. R. W. Sindall, an English paper authority, some years ago defined linen paper as paper "containing no fibrous ingredient except linen rag." In America at the present time the word linen seems to bear little relation to the raw material used. Linen paper is usually made out of cotton rags, but may contain some linen rags. It may be stated safely that no paper is made in this country entirely out of linen rags, except on orders for certain special purposes. A cotton-rag paper ordinarily serves the purpose of writing just as well as a linen-rag paper. On the whole, the word linen may be taken to denote a high-class product; certain high-grade ledger paper, for instance, is termed linen ledger, though it may or may not contain a small percentage of linen rag.

Finishes—linen, kid, etc.—The term linen finish, however, has a more definite significance. A linen finish may be applied to any writing paper. The sheets of paper from the drying lofts, still slightly damp from the animal-glue sizing bath, are placed between

sheets of pure linen cloth, a sheet of zinc or heavy tin being placed between each two sheets of linen. When a pile of paper, linen, and metal sheets about 4 inches thick has been built up it is passed between press rolls, the surface of the linen cloth being thus imparted to the paper. This finish may be given any writing paper, except ledger and record paper. It is occasionally, but not often, given to bond paper. Other finishes such as kid, vellum, and antique are often given. Kid and vellum finishes resemble prepared kid and calfskin, respectively. Antique finish imparts a soft velvety feeling to the paper.

These finishes, given writing paper, are to some extent used also in making the best qualities of book paper.
